1 GENERAL DESCRIPTION

The NuMicro® M051 series 32-bit microcontroller is embedded with ARM® Cortex®-M0 core for industrial control and applications which need rich communication interfaces. The M051 series includes the following part numbers: M052xBN/xDN/xDE, M054xBN/xDN/xDE, M058xBN/xDN/xDE and M0516xBN/xDN/xDE.

The NuMicro® M051 series can run up to 50 MHz and operate at 2.5V ~ 5.5V, -40°C ~ 85°C, while M05xxDE operates at -40°C ~ 105°C, and thus can afford to support a variety of industrial control and applications which need high CPU performance. The M051 series offers 8K/16K/32K/64K-bytes flash, 4K-byte Data Flash, 4K-byte flash for the ISP, and 4K-byte SRAM.

Many system level peripheral functions, such as I/O Port, EBI (External Bus Interface), Timer, UART, SPI, I²C, PWM, ADC, Watchdog Timer, Window Watchdog Timer (M05xxDN/DE only), Analog Comparator and Brown-out Detector, have been incorporated into the M051 series in order to reduce component count, board space and system cost. These useful functions make the M051 series powerful for a wide range of applications.

Additionally, the NuMicro® M051 series is equipped with ISP (In-System Programming) and ICP (In-Circuit Programming) functions, and IAP (In-Application Programming) (M05xxDN/DE only), which allow the user to update the program memory without removing the chip from the actual end product.

Item	M05xxBN	M05xxDN	M05xxDE
Operating Temperature	-40°C ~ 85°C	-40°C ~ 85°C	-40°C ~ 105°C
Hardware Divider	-	●	●
IAP Mode	-	●	●
Window WDT	-	●	●
Analog Comparators	2	4	4
Configurable I/O mode after POR	-	●	●
I ² C	1	2 (Supports Wake-up)	2 (Supports Wake-up)
SPI	- Only Supports HCLK as SPI clock source - No FIFO	- Supports HCLK and PLL as SPI clock source - 4-level FIFO	- Supports HCLK and PLL as SPI clock source - 4-level FIFO
PWM and ADC	PWM cannot trigger ADC	- PWM can trigger ADC conversion	- PWM can trigger ADC conversion

Table 1-1 M05xxBN, M05xxDN and M05xxDE Difference List

2 FEATURES

- Core
 - ARM® Cortex®-M0 core running up to 50 MHz
 - One 24-bit system timer
 - Supports Low Power Sleep mode
 - A single-cycle 32-bit hardware multiplier
 - NVIC for the 32 interrupt inputs, each with 4-levels of priority
 - Supports Serial Wire Debug (SWD) interface and two watchpoints/four breakpoints
 - Provides hardware divider (M05xxDN/DE only) and supports signed 32-bit dividend, 16-bit divisor operation
- Wide Operating Voltage Range: 2.5V to 5.5V
- Memory
 - 8KB/16KB/32KB/64KB Flash for program memory (APROM)
 - 4KB Flash for data memory (Data Flash)
 - 4KB Flash for loader (LDROM)
 - 4KB SRAM for internal scratch-pad RAM (SRAM)
- Clock Control
 - Programmable system clock source
 - 22.1184 MHz internal oscillator
 - 4~24 MHz external crystal input
 - 10 kHz low-power oscillator for Watchdog Timer and wake-up in Sleep mode
 - PLL allows CPU operation up to the maximum 50 MHz
- I/O Port
 - Up to 40 general-purpose I/O (GPIO) pins for LQFP-48 package
 - Four I/O modes:
 - ◆ Quasi-bidirectional
 - ◆ Push-Pull output
 - ◆ Open-Drain output
 - ◆ Input only with high impedance
 - TTL/Schmitt trigger input selectable
 - I/O pin can be configured as interrupt source with edge/level setting
 - Supports high driver and high sink I/O mode
 - Configurable I/O mode after POR (M05xxDN/DE only)
- Timer
 - Provides four channel 32-bit timers; one 8-bit pre-scale counter with 24-bit up-timer for each timer
 - Independent clock source for each timer
 - 24-bit timer value is readable through TDR (Timer Data Register)
 - Provides One-shot, Periodic and Toggle operation modes
 - Provides event counter function
 - Provides external capture/reset counter function
 - Additional functions for M05xxDN/DE:
 - ◆ Two more timer clock sources from external trigger and internal 10 kHz
 - ◆ TIMER wake-up function
 - ◆ External capture input source selected from ACMP or TxEX
 - ◆ Toggle mode output pins selected from TxEX or TMx
 - ◆ Inter-Timer trigger mode

- WDT (Watchdog Timer)
 - Multiple clock sources
 - Supports wake-up from Power-down or Sleep mode
 - Interrupt or reset selectable on watchdog time-out
 - Time-out reset delay period time can be selected (M05xxDN/DE only)
- WWDT (Window Watchdog Timer) (M05xxDN/DE only)
 - 6-bit down counter with 11-bit pre-scale for wide range window selected
- PWM
 - Up to four built-in 16-bit PWM generators, providing eight PWM outputs or four complementary paired PWM outputs
 - Individual clock source, clock divider, 8-bit pre-scalar and dead-zone generator for each PWM generator
 - PWM interrupt synchronized to PWM period
 - 16-bit digital Capture timers (shared with PWM timers) with rising/falling capture inputs
 - Supports capture interrupt
 - Additional functions for M05xxDN/DE:
 - ◆ Internal 10 kHz to PWM clock source
 - ◆ Polar inverse function
 - ◆ Center-aligned type function
 - ◆ Timer duty interrupt enable function
 - ◆ Two kinds of PWM interrupt period type selection
 - ◆ Two kinds of PWM interrupt duty type selection
 - ◆ Period/duty trigger ADC function
 - ◆ PWM Timer synchronous start function
- UART
 - Up to two sets of UART devices
 - Programmable baud-rate generator
 - Buffered receiver and transmitter, each with 15 bytes FIFO
 - Optional flow control function (CTS and RTS)
 - Supports IrDA(SIR) function
 - Supports RS485 function
 - Supports LIN function
- SPI
 - Up to two sets of SPI devices
 - Supports Master/Slave mode
 - Full-duplex synchronous serial data transfer
 - Provides 3 wire function
 - Variable length of transfer data from 8 to 32 bits
 - MSB or LSB first data transfer
 - Rx latching data can be either at rising edge or at falling edge of serial clock
 - Tx sending data can be either at rising edge or at falling edge of serial clock
 - Supports Byte Suspend mode in 32-bit transmission
 - Additional functions for M05xxDN/DE:
 - ◆ PLL clock source
 - ◆ 4-level depth FIFO buffer for better performance and flexibility in SPI Burst Transfer mode
- I²C
 - I²C modules

- ◆ M05xxBN: up to one set
 - ◆ M05xxDN/DE: up to two sets
 - Supports Master/Slave mode
 - Bidirectional data transfer between masters and slaves
 - Multi-master bus (no central master)
 - Arbitration between simultaneously transmitting masters without corruption of serial data on the bus
 - Serial clock synchronization allows devices with different bit rates to communicate via one serial bus
 - Serial clock synchronization can be used as a handshake mechanism to suspend and resume serial transfer
 - Programmable clocks allow versatile rate control
 - Supports multiple address recognition (four slave addresses with mask option)
- ADC
 - 12-bit SAR ADC
 - Up to 8-ch single-ended input or 4-ch differential input
 - Supports Single mode/Burst mode/Single-cycle Scan mode/Continuous Scan mode
 - Supports 2' complement/un-signed format in differential mode conversion results
 - Each channel with an individual result register
 - Supports conversion value monitoring (or comparison) for threshold voltage detection
 - Conversion started either by software trigger or external pin trigger
 - Additional functions for M05xxDN/DE:
 - ◆ A/D conversion started by PWM center-aligned trigger or edge-aligned trigger
 - ◆ PWM trigger delay function
 - ◆ Supports conversion result with signed format in Differential input and Burst mode
 - Analog Comparator
 - Comparator analog modules
 - ◆ M05xxBN: up to two sets
 - ◆ M05xxDN/DE: up to four sets
 - External input or internal band-gap voltage selectable at negative node
 - Interrupt when compared results change
 - Power-down wake-up
 - EBI (External Bus Interface) for external memory-mapped device access
 - Accessible space: 64 KB in 8-bit mode or 128 KB in 16-bit mode
 - Supports 8-bit or 16-bit data width
 - Supports byte-write in 16-bit data width
 - ISP (In-System Programming) and ICP (In-Circuit Programming)
 - IAP (In-Application Programming) (M05xxDN/DE only)
 - One built-in temperature sensor with 1°C resolution
 - BOD (Brown-out Detector)
 - With 4 levels: 4.4V/3.7V/2.7V/2.2V
 - Supports Brown-out interrupt and reset option
 - 96-bit unique ID
 - LVR (Low Voltage Reset)

- Threshold voltage level: 2.0V
- Operating Temperature:
 - M05xxBN: -40°C ~85°C
 - M05xxDN: -40°C ~85°C
 - M05xxDE: -40°C ~105°C
- Packages:
 - Green package (RoHS)
 - 48-pin LQFP, 33-pin QFN

3 ABBREVIATIONS

3.1 List of Abbreviations

Acronym	Description
ACMP	Analog Comparator Controller
ADC	Analog-to-Digital Converter
AES	Advanced Encryption Standard
APB	Advanced Peripheral Bus
AHB	Advanced High-Performance Bus
BOD	Brown-out Detection
CAN	Controller Area Network
DAP	Debug Access Port
DES	Data Encryption Standard
EBI	External Bus Interface
EPWM	Enhanced Pulse Width Modulation
FIFO	First In, First Out
FMC	Flash Memory Controller
FPU	Floating-point Unit
GPIO	General-Purpose Input/Output
HCLK	The Clock of Advanced High-Performance Bus
HIRC	22.1184 MHz Internal High Speed RC Oscillator
HXT	4~24 MHz External High Speed Crystal Oscillator
IAP	In Application Programming
ICP	In Circuit Programming
ISP	In System Programming
LDO	Low Dropout Regulator
LIN	Local Interconnect Network
LIRC	10 kHz internal low speed RC oscillator (LIRC)
MPU	Memory Protection Unit
NVIC	Nested Vectored Interrupt Controller
PCLK	The Clock of Advanced Peripheral Bus
PDMA	Peripheral Direct Memory Access
PLL	Phase-Locked Loop
PWM	Pulse Width Modulation
QEI	Quadrature Encoder Interface
SDIO	Secure Digital Input/Output

SPI	Serial Peripheral Interface
SPS	Samples per Second
TDES	Triple Data Encryption Standard
TMR	Timer Controller
UART	Universal Asynchronous Receiver/Transmitter
UCID	Unique Customer ID
USB	Universal Serial Bus
WDT	Watchdog Timer
WWDT	Window Watchdog Timer

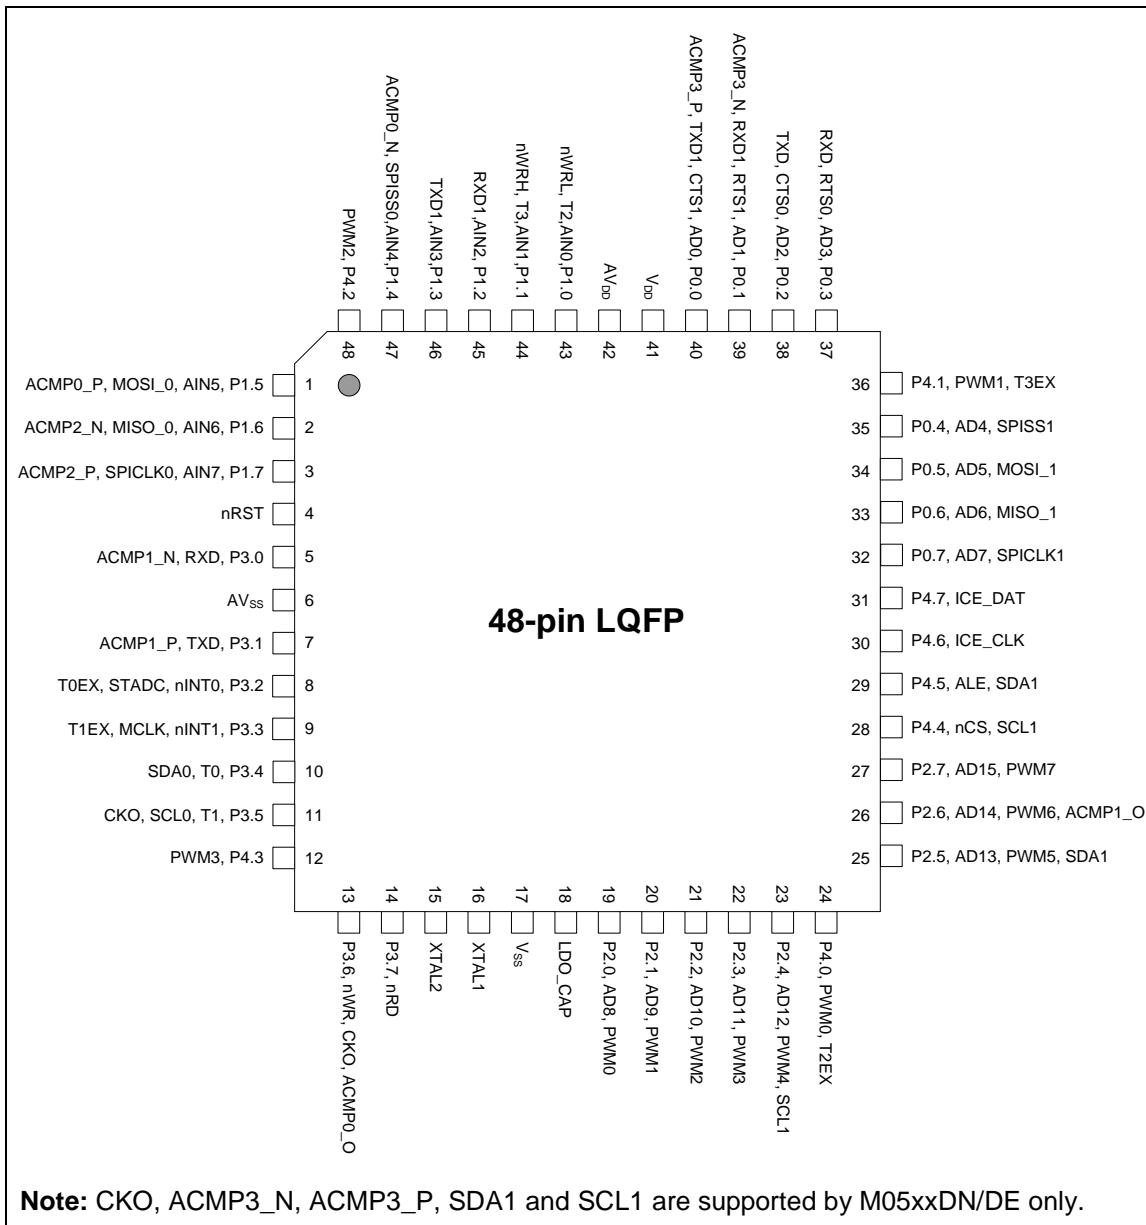

Figure 4-3 NuMicro® M051 Series LQFP-48 Pin Diagram

4.5 Pin Description

Pin Number		Symbol	Alternate Function			Type ^[1]	Description
QFN33	LQFP48		1	2	3		
11	16	XTAL1				I (ST)	External 4~24 MHz (high speed) crystal input pin.
10	15	XTAL2				O	External 4~24 MHz (high speed) crystal output pin.
27	41	V _{DD}				P	Power supply to I/O ports and LDO source for internal PLL and digital circuit.
12	17	V _{SS}				P	Ground pin for digital circuit.
33							
28	42	A V _{DD}				P	Power supply to internal analog circuit.
4	6	A V _{SS}				P	Analog Ground pin for analog circuit.
13	18	LDO_CAP				P	LDO output pin. Note: This pin needs to be connected with a 1uF capacitor.
2	4	nRST				I (ST)	The nRST pin is a Schmitt trigger input pin for hardware device reset. A “Low” on this pin for 768 clock counter of Internal RC 22M while the system clock is running will reset the device. The nRST pin has an internal pull-up resistor allowing power-on reset by simply connecting an external capacitor to GND.
26	40	P0.0	CTS1	AD0	TXD1 ^[2] , ACMP3_P	I/O	The P0.0 ~ P0.7 pins are called Port 0. Port 0 is a general purpose I/O port, which can be configured as Input, Output, Quasi Bi-direction and Open-drain mode.
25	39	P0.1	RTS1	AD1	RXD1 ^[2] , ACMP3_N	/O	Port 0 supports multi-function pins, including CTS1, RTS1, CTS0, RTS0, SPISS1, MOSI_1, MISO_1, SPICLK1, AD0 ~ AD7, TXD1, RXD1, TXD, RXD, ACMP3_P, and ACMP3_N.
NC	38	P0.2	CTS0	AD2	TXD ^[2]	I/O	AD0 ~ AD7 belong to EBI function for external memory accessing.
NC	37	P0.3	RTS0	AD3	RXD ^[2]	I/O	The SPISS1, MOSI_1, MISO_1, and SPICLK1 pins are for SPI function.
24	35	P0.4	SPISS1	AD4		I/O	The CTS0 and CTS1 pins are clear to send input pin for UART0/1.
23	34	P0.5	MOSI_1	AD5		I/O	The RTS0 and RTS1 pins are Request to Send output pin for UART0/1.
22	33	P0.6	MISO_1	AD6		I/O	The RXD and TXD pins are for UART0 function.
21	32	P0.7	SPICLK1	AD7		I/O	The RXD1 and TXD1 pins are for UART1 function.
							The ACMP3_N and ACMP3_P pins are for ACMP3 negative/positive inputs.
29	43	P1.0	T2	AIN0	nWRL	I/O	The P1.0 ~ P1.7 pins are called Port 1. Port 1 is a general purpose I/O port, which can be configured as Input, Output, Quasi-bidirectional and Open-drain mode.
NC	44	P1.1	T3	AIN1	nWRH	I/O	

30	45	P1.2	RXD1 ^[2]	AIN2		I/O	Port 1 supports multi-function pins, including T2, T3, RXD1, TXD1, SPISS0, MOSI_0, MISO_0, SPICLK0, AIN0 ~ AIN7, nWRL, nWRH, ACMP0_N, ACMP0_P, ACMP2_N, and ACMP2_P.
31	46	P1.3	TXD1 ^[2]	AIN3		I/O	The SPISS0, MOSI_0, MISO_0, and SPICLK0 pins are for SPI function.
32	47	P1.4	SPISS0	AIN4	ACMP0_N	I/O	The AIN0 ~ AIN7 pins are for 12 bits ADC function.
1	1	P1.5	MOSI_0	AIN5	ACMP0_P	I/O	The RXD1 and TXD1 pins are for UART1 function.
NC	2	P1.6	MISO_0	AIN6	ACMP2_N	I/O	The nWRL and nWRH pins are for low/high byte write enable output in 16-bit data width of EBI.
NC	3	P1.7	SPICLK0	AIN7	ACMP2_P	I/O	The ACMP0_N and ACMP0_P pins are for ACMP0 negative/positive inputs. The ACMP2_N and ACMP2_P pins are for ACMP2 negative/positive inputs. The T2 and T3 pins are for Timer2/3 external even counter input and toggle mode output.
NC	19	P2.0	PWM0 ^[2]	AD8		I/O	The P2.0 ~ P2.7 pins are called Port 2. Port 2 is a general purpose I/O port, which can be configured as Input, Output, Quasi-bidirectional and Open-drain mode.
NC	20	P2.1	PWM1 ^[2]	AD9		I/O	Port 2 supports multi-function pins, including PWM0 ~ PWM7, AD8 ~ AD15, SCL1, SDA1 and ACMP1_O.
14	21	P2.2	PWM2 ^[2]	AD10		I/O	The PWM0~PWM7 pins are for PWM function in the LQFP48 package.
15	22	P2.3	PWM3 ^[2]	AD11		I/O	AD8 ~ AD15 belong to EBI function for external memory accessing.
16	23	P2.4	PWM4	AD12	SCL1 ^[2]	I/O	The SDA1 and SCL1 pins are for I ² C1 function and both of them are open-drain.
17	25	P2.5	PWM5	AD13	SDA1 ^[2]	I/O	The ACMP1_O pin is the output of ACMP1.
18	26	P2.6	PWM6	AD14	ACMP1_O	I/O	
NC	27	P2.7	PWM7	AD15		I/O	
3	5	P3.0	RXD ^[2]		ACMP1_N	I/O	The P3.0 ~ P3.7 pins are called Port 3. Port 3 is a general purpose I/O port, which can be configured as Input, Output, Quasi-bidirectional and Open-drain mode.
5	7	P3.1	TXD ^[2]		ACMP1_P	I/O	Port 3 supports multi-function pins, including RXD, TXD, nINT0, nINT1, T0, T1, nWR, nRD, STADC, MCLK, SDA0, SCL0, CKO, ACMP1_N, ACMP1_P, T0EX, T1EX, ACMP0_O.
6	8	P3.2	nINT0	STADC	T0EX	I/O	The RXD and TXD pins are for UART0 function.
NC	9	P3.3	nINT1	MCLK	T1EX	I/O	The nINT0 and nINT1 pins are for external interrupt input.
7	10	P3.4	T0	SDA0		I/O	The T0 and T1 pins are for Timer0/1 external even counter input and toggle mode output.
8	11	P3.5	T1	SCL0	CKO ^[2]	I/O	The nWR, nRD and MCLK are for EBI function.
9	13	P3.6	nWR	CKO	ACMP0_O	I/O	The STADC pin is for ADC external trigger input.
NC	14	P3.7	nRD			I/O	The SDA0 and SCL0 pins are for I ² C function and both of them are open-drain.
NC	14	P3.7	nRD			I/O	The CKO is clock output pin for clock monitor. The ACMP1_N and ACMP1_P pins are for ACMP1 negative/positive inputs. The T0EX and T1EX pins are for external capture/reset trigger input of Timer0/1. The ACMP0_O pin is the output of Analog ACMP0.
NC	24	P4.0	PWM0 ^[2]		T2EX	I/O	The P4.0 ~ P4.7 pins are called Port 4. Port 4 is a general

NC	36	P4.1	PWM1 ^[2]		T3EX	I/O	<p>purpose I/O port, which can be configured as Input, Output, Quasi-bidirectional and Open-drain mode.</p> <p>Port 3 supports multi-function pins, including PWM0 ~ PWM3, nCS, ALE, ICE_CLK, ICE_DAT, SCL1, SDA1, T2EX and T3EX.</p> <p>The PWM0 ~ PWM3 pins are for PWM function.</p> <p>The nCS and ALE pins are for EBI function.</p> <p>The ICE_CLK and ICE_DAT pins are for Serial Wire Debug Interface.</p> <p>The SDA1 and SCL1 pins are for I²C1 function and both of them are open-drain.</p> <p>The T2EX and T3EX pins are for external capture/reset trigger input of Timer2/3.</p>
NC	48	P4.2	PWM2 ^[2]			I/O	
NC	12	P4.3	PWM3 ^[2]			I/O	
NC	28	P4.4	nCS	SCL1		I/O	
NC	29	P4.5	ALE	SDA1		I/O	
19	30	P4.6	ICE_CLK			I/O	
20	31	P4.7	ICE_DAT			I/O	

Note 1: I/O type description. I: Input, O: Output, I/O: Quasi-bidirectional, D: Open-drain, P: Power pins, ST: Schmitt trigger.

Note 2: The PWM0 ~ PWM3, RXD, TXD, RXD1, TXD1, SCL1, SDA1 and CKO can be assigned to different pins. However, a pin function can only be assigned to a pin at the same time, i.e. software cannot assign RXD to P0.3 and P3.0 at the same time.

5 BLOCK DIAGRAM

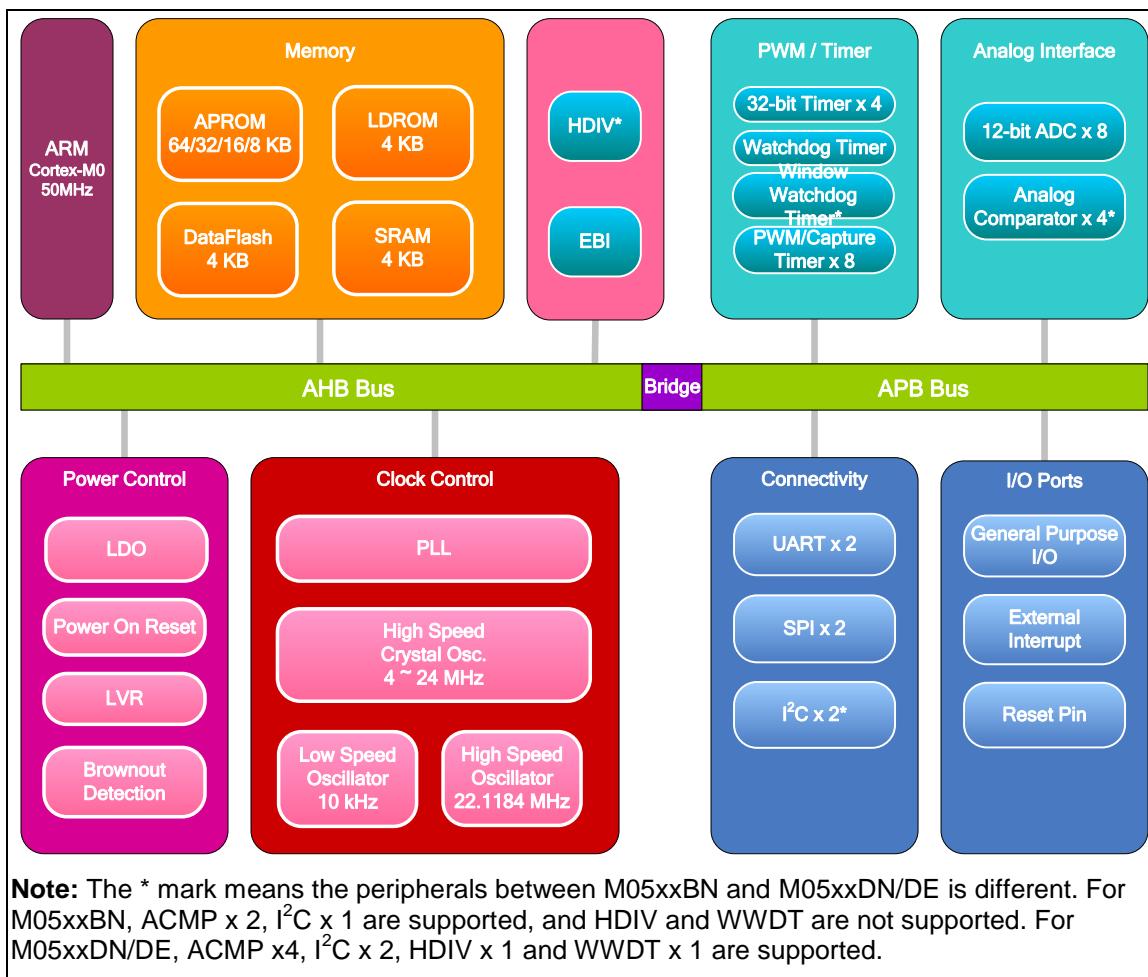

Figure 5-1 NuMicro® M051 Series Block Diagram

6 FUNCTIONAL DESCRIPTION

6.1 ARM® Cortex®-M0 Core

The Cortex®-M0 processor is a configurable, multistage, 32-bit RISC processor, which has an AMBA AHB-Lite interface and includes an NVIC component. It also has optional hardware debug functionality. The processor can execute Thumb code and is compatible with other Cortex®-M profile processor. The profile supports two modes - Thread mode and Handler mode. Handler mode is entered as a result of an exception. An exception return can only be issued in Handler mode. Thread mode is entered on Reset, and can be entered as a result of an exception return. The following figure shows the functional controller of processor.

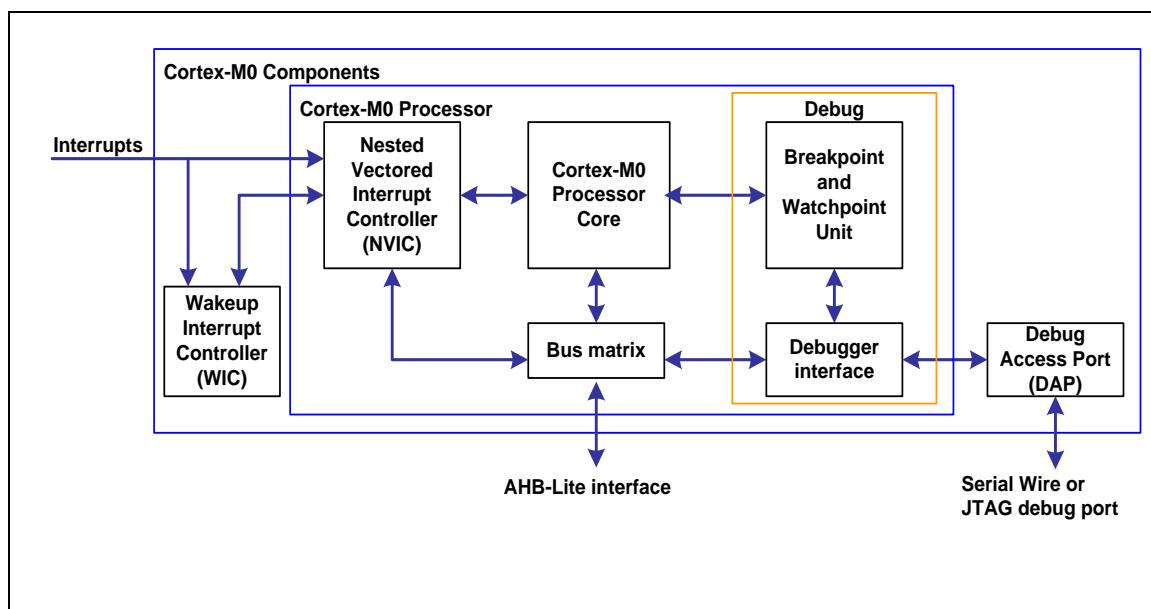

Figure 6-1 Functional Block Diagram

The implemented device provides:

- A low gate count processor:
 - ARMv6-M Thumb® instruction set
 - Thumb-2 technology
 - ARMv6-M compliant 24-bit SysTick timer
 - A 32-bit hardware multiplier
 - System interface supported with little-endian data accesses
 - Ability to have deterministic, fixed-latency, interrupt handling
 - Load/store-multiples and multicycle-multiplies that can be abandoned and restarted to facilitate rapid interrupt handling
 - C Application Binary Interface compliant exception model. This is the ARMv6-M, C Application Binary Interface (C-ABI) compliant exception model that enables the use of pure C functions as interrupt handlers
 - Low Power Sleep mode entry using the Wait For Interrupt (WFI), Wait For Event (WFE) instructions, or return from interrupt sleep-on-exit feature

- NVIC:
 - 32 external interrupt inputs, each with four levels of priority
 - Dedicated Non-maskable Interrupt (NMI) input
 - Supports for both level-sensitive and pulse-sensitive interrupt lines
 - Supports Wake-up Interrupt Controller (WIC) and, providing Ultra-low Power Sleep mode
- Debug support:
 - Four hardware breakpoints
 - Two watchpoints
 - Program Counter Sampling Register (PCSR) for non-intrusive code profiling
 - Single step and vector catch capabilities
- Bus interfaces:
 - Single 32-bit AMBA-3 AHB-Lite system interface that provides simple integration to all system peripherals and memory
 - Single 32-bit slave port that supports the DAP (Debug Access Port)

6.2 System Manager

6.2.1 Overview

System management includes the following sections:

- System Resets
- System Power Architecture
- System Memory Map
- System management registers for Part Number ID, chip reset and on-chip controllers reset, and multi-functional pin control
- System Timer (SysTick)
- Nested Vectored Interrupt Controller (NVIC)
- System Control registers

6.2.2 System Reset

The system reset can be issued by one of the following listed events. For these reset event flags can be read by RSTSRC register.

- Hardware Reset
 - Power-on Reset (POR)
 - Low level on the Reset Pin (nRST)
 - Watchdog Timer Time-out Reset (WDT)
 - Low Voltage Reset (LVR)
 - Brown-out Detector Reset (BOD)
- Software Reset
 - MCU Reset - SYSRESETREQ(AIRCR[2])
 - Cortex-M0 Core One-shot Reset - CPU_RST(IPRSTC1[1])
 - Chip One-shot Reset - CHIP_RST(IPRSTC1[0])

Note: ISPCON.BS keeps the original value after MCU Reset and CPU Reset.

6.2.3 System Power Architecture

In this chip, the power distribution is divided into two segments.

- Analog power from AV_{DD} and AV_{SS} provides the power for analog components operation. AV_{DD} must be equal to V_{DD} to avoid leakage current.
- Digital power from V_{DD} and V_{SS} supplies the power to the I/O pins and internal regulator which provides a fixed 1.8 V power for digital operation.

The output of internal voltage regulator, LDO_CAP, requires an external capacitor which should be located close to the corresponding pin. Analog power (AV_{DD}) should be the same voltage level as the digital power (V_{DD}). The following figure shows the power distribution of the M051 series.

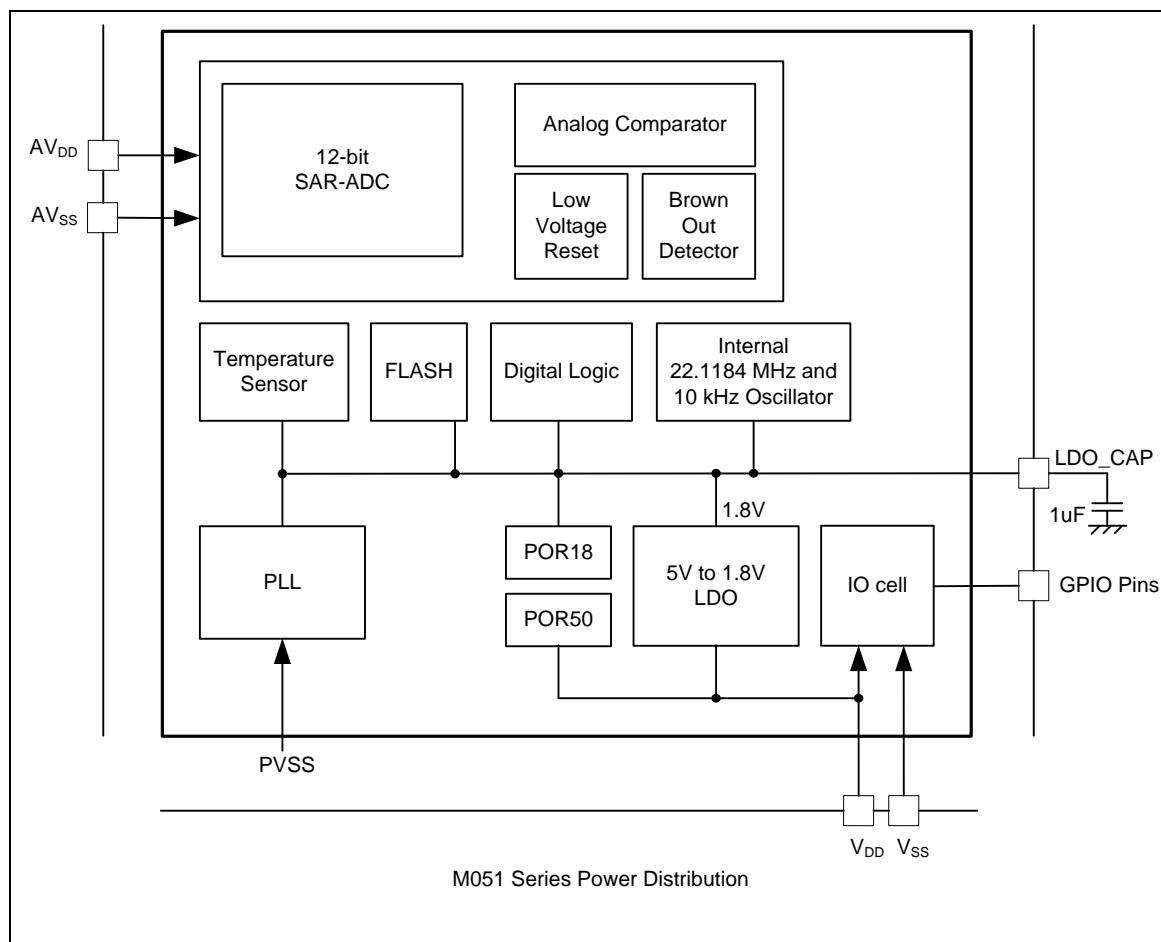

Figure 6-2 NuMicro® M051 Series Power Architecture Diagram

6.2.4 System Memory Map

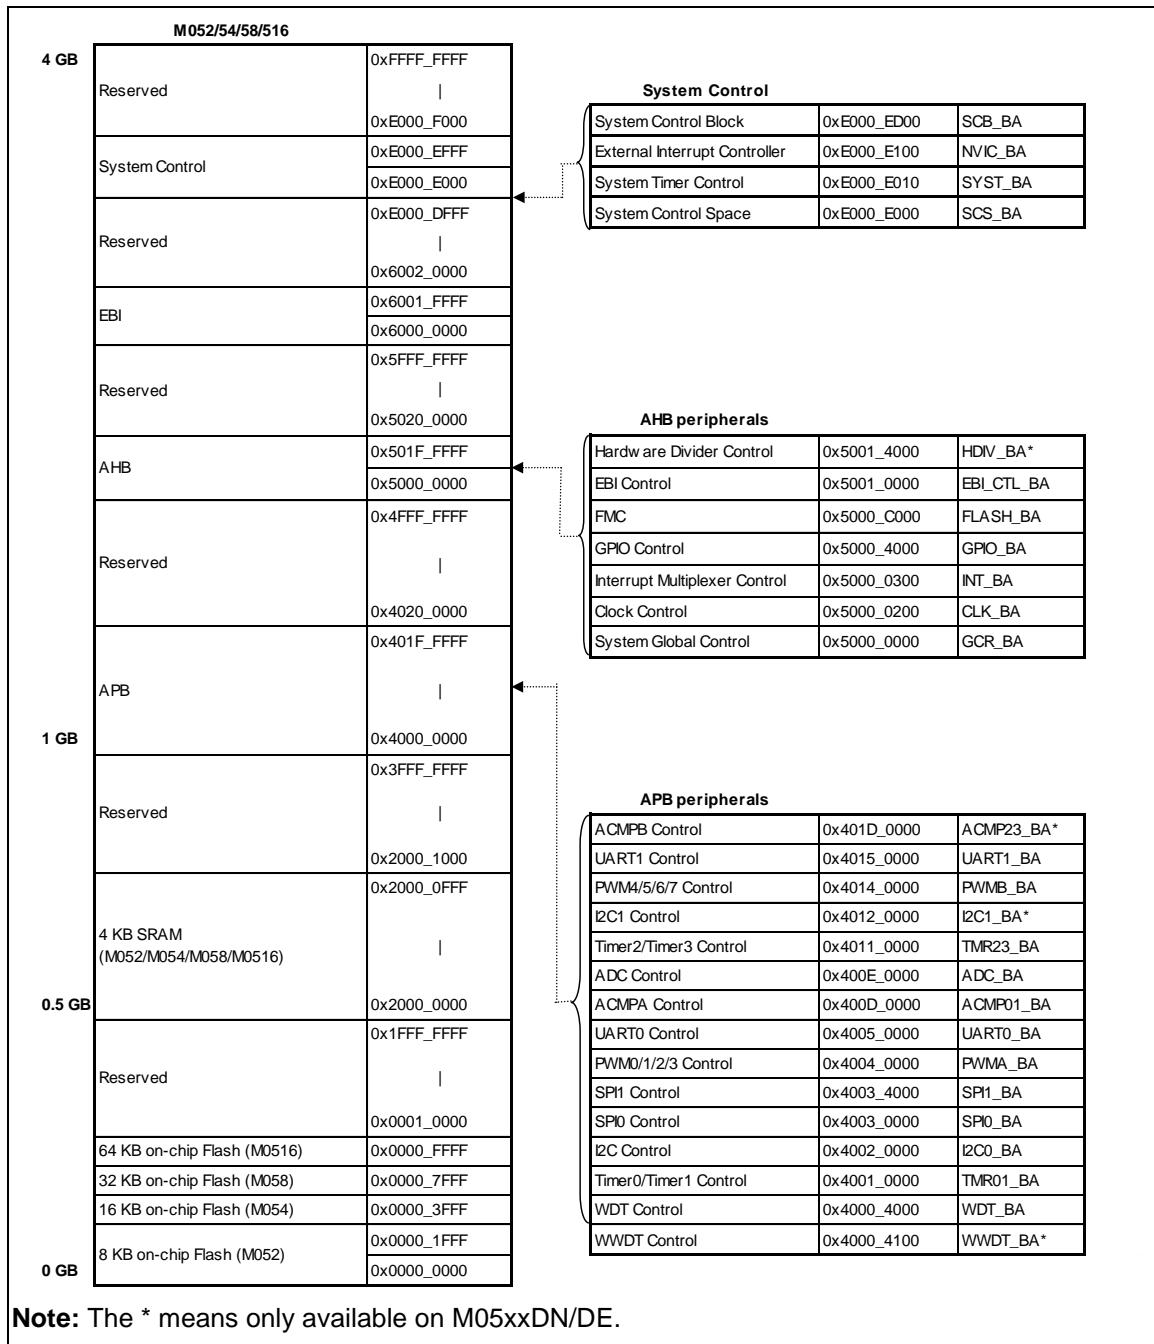

The NuMicro® M051 series provides 4G-byte addressing space. The addressing space assigned to each on-chip controllers are shown in the following table. The detailed register definition, addressing space, and programming details will be described in the following sections for each on-chip peripheral. The NuMicro® M051 series only supports little-endian data format.

Addressing Space	Token	Modules
Flash & SRAM Memory Space		
0x0000_0000 – 0x0000_FFFF	FLASH_BA	FLASH Memory Space (64KB)
0x2000_0000 – 0x2000_0FFF	SRAM_BA	SRAM Memory Space (4 KB)
EBI Space (0x6000_0000 ~ 0x6001_FFFF)		
0x6000_0000 – 0x6001_FFFF	EBI_BA	External Memory Space (128 KB)
AHB Modules Space (0x5000_0000 – 0x501F_FFFF)		
0x5000_0000 – 0x5000_01FF	GCR_BA	System Global Control Registers
0x5000_0200 – 0x5000_02FF	CLK_BA	Clock Control Registers
0x5000_0300 – 0x5000_03FF	INT_BA	Interrupt Multiplexer Control Registers
0x5000_4000 – 0x5000_7FFF	GPIO_BA	GPIO (P0~P4) Control Registers
0x5000_C000 – 0x5000_FFFF	FMC_BA	Flash Memory Control Registers
0x5001_0000 – 0x5001_03FF	EBI_CTL_BA	EBI Control Registers
0x5001_4000 – 0x5001_7FFF	HDIV_BA	Hardware Divider Register (M05xxDN/DE Only)
APB Modules Space (0x4000_0000 ~ 0x400F_FFFF)		
0x4000_4000 – 0x4000_00FF	WDT_BA	Watchdog Timer Control Registers
0x4000_4100 – 0x4000_7FFF	WWDT_BA	Window Watchdog Timer Control Registers (M05xxDN/DE Only)
0x4001_0000 – 0x4001_3FFF	TMR01_BA	Timer0/Timer1 Control Registers
0x4002_0000 – 0x4002_3FFF	I2C0_BA	I ² C0 Interface Control Registers
0x4003_0000 – 0x4003_3FFF	SPI0_BA	SPI0 with master/slave function Control Registers
0x4003_4000 – 0x4003_7FFF	SPI1_BA	SPI1 with master/slave function Control Registers
0x4004_0000 – 0x4004_3FFF	PWMA_BA	PWM0/1/2/3 Control Registers
0x4005_0000 – 0x4005_3FFF	UART0_BA	UART0 Control Registers
0x400D_0000 – 0x400D_3FFF	ACMP01_BA	Analog Comparator 0/1 Control Registers
0x400E_0000 – 0x400E_FFFF	ADC_BA	Analog-Digital-Converter (ADC) Control Registers
0x4011_0000 – 0x4011_3FFF	TMR23_BA	Timer2/Timer3 Control Registers
0x4012_0000 – 0x4012_3FFF	I2C1_BA	I ² C1 Interface Control Registers (M05xxDN/DE Only)
0x4014_0000 – 0x4014_3FFF	PWMB_BA	PWM4/5/6/7 Control Registers
0x4015_0000 – 0x4015_3FFF	UART1_BA	UART1 Control Registers
0x401D_0000 – 0x401D_3FFF	ACMP23_BA	Analog Comparator 2/3 Control Registers (M05xxDN/DE Only)
System Control Space (0xE000_E000 ~ 0xE000_EFFF)		

0xE000_E010 – 0xE000_E0FF	SYST_BA	System Timer Control Registers
0xE000_E100 – 0xE000_ECFF	NVIC_BA	External Interrupt Controller Control Registers
0xE000_ED00 – 0xE000_ED8F	SCB_BA	System Control Block Registers

System Reset Source Register (RSTSRC)

This register provides specific information for software to identify this chip's reset source from the last operation.

Register	Offset	R/W	Description				Reset Value
RSTSRC	GCR_BA+0x04	R/W	System Reset Source Register				0x0000_00XX

RSTS_CPU	Reserved	RSTS MCU	RSTS_BOD	RSTS_LVR	RSTS_WDT	RSTS_RESET	RSTS_POR

Bits	Description	
[31:8]	Reserved	Reserved.
[7]	RSTS_CPU	CPU Reset Flag The RSTS_CPU flag is set by hardware if software writes CPU_RST (IPRSTC1[1]) 1 to reset Cortex®-M0 core and Flash memory controller (FMC). 0 = No reset from CPU. 1 = Cortex®-M0 core and FMC are reset by software setting CPU_RST to 1. Note: Write 1 to clear this bit to 0.
[6]	Reserved	Reserved.
[5]	RSTS MCU	MCU Reset Flag The RSTS MCU flag is set by the “reset signal” from the Cortex®-M0 core to indicate the previous reset source. 0 = No reset from Cortex®-M0. 1 = The Cortex®-M0 had issued the reset signal to reset the system by writing 1 to bit SYSRESETREQ (AIRCR[2], Application Interrupt and Reset Control Register, address = 0xE000ED0C) in system control registers of Cortex®-M0 core. Note: Write 1 to clear this bit to 0.
[4]	RSTS_BOD	Brown-out Detector Reset Flag The RSTS_BOD flag is set by the “reset signal” from the Brown-out Detector to indicate the previous reset source. 0 = No reset from BOD. 1 = The BOD had issued the reset signal to reset the system. Note: Write 1 to clear this bit to 0.
[3]	RSTS_LVR	Low Voltage Reset Flag The RSTS_LVR flag is set by the “reset signal” from the Low-Voltage-Reset controller to indicate the previous reset source.

		0 = No reset from LVR. 1 = The LVR controller had issued the reset signal to reset the system. Note: Write 1 to clear this bit to 0.
[2]	RSTS_WDT	Watchdog Reset Flag The RSTS_WDT flag is set by the “reset signal” from the watchdog timer to indicate the previous reset source. 0 = No reset from watchdog timer. 1 = The watchdog timer had issued the reset signal to reset the system. Note: Write 1 to clear this bit to 0.
[1]	RSTS_RESET	Reset Pin Reset Flag The RSTS_RESET flag is set by the “reset signal” from the nRST pin to indicate the previous reset source. 0 = No reset from the nRST pin. 1 = The nRST pin had issued the reset signal to reset the system. Note: Write 1 to clear this bit to 0.
[0]	RSTS_POR	Power-on Reset Flag The RSTS_POR flag is set by the “reset signal” from the Power-on Reset (POR) controller or bit CHIP_RST (IPRSTC1[0]) to indicate the previous reset source. 0 = No reset from POR or CHIP_RST. 1 = The Power-on Reset (POR) or CHIP_RST had issued the reset signal to reset the system. Note: Write 1 to clear this bit to 0.

Peripheral Reset Control Register1 (IPRSTC1)

Register	Offset	R/W	Description					Reset Value

Reserved			HDIV_RST	EBI_RST	Reserved	CPU_RST	CHIP_RST

Bits	Description	
[31:5]	Reserved	Reserved.
[4]	HDIV_RST	<p>HDIV Controller Reset (Write Protect) (M05xxDN/DE Only)</p> <p>Set this bit to 1 will generate a reset signal to the hardware divider. User need to set this bit to 0 to release from the reset state.</p> <p>0 = Hardware divider controller normal operation. 1 = Hardware divider controller reset.</p> <p>Note: This bit is the protected bit, and programming it needs to write “59h”, “16h”, and “88h” to address 0x5000_0100 to disable register protection. Refer to the register REGWRPROT at address GCR_BA+0x100.</p>
[3]	EBI_RST	<p>EBI Controller Reset (Write Protect)</p> <p>Set this bit to 1 will generate a reset signal to the EBI. User needs to set this bit to 0 to release from the reset state.</p> <p>0 = EBI controller normal operation. 1 = EBI controller reset.</p> <p>Note: This bit is the protected bit, and programming it needs to write “59h”, “16h”, and “88h” to address 0x5000_0100 to disable register protection. Refer to the register REGWRPROT at address GCR_BA+0x100.</p>
[2]	Reserved	Reserved.
[1]	CPU_RST	<p>Cortex-m0 Core One-shot Reset (Write Protect)</p> <p>Setting this bit will only reset the Cortex-M0 core and Flash Memory Controller (FMC), and this bit will automatically return 0 after the two clock cycles.</p> <p>0 = Cortex-M0 core normal operation. 1 = Cortex-M0 core one-shot reset.</p> <p>Note: This bit is the protected bit, and programming it needs to write “59h”, “16h”, and “88h” to address 0x5000_0100 to disable register protection. Refer to the register REGWRPROT at address GCR_BA+0x100.</p>
[0]	CHIP_RST	<p>Chip One-shot Reset (Write Protect)</p> <p>Setting this bit will reset the whole chip, including Cortex-M0 core and all peripherals, and this bit will automatically return to 0 after the 2 clock cycles.</p> <p>The CHIP_RST is the same as the POR reset. All the chip controllers are reset and the chip</p>

		<p>setting from CONFIG0 are also reload.</p> <p>0 = Chip normal operation.</p> <p>1 = Chip one-shot reset.</p> <p>Note: This bit is the protected bit, and programming it needs to write “59h”, “16h”, and “88h” to address 0x5000_0100 to disable register protection. Refer to the register REGWRPROT at address GCR_BA+0x100.</p>
--	--	---

Peripheral Reset Control Register2 (IPRSTC2)

Setting these bits “1” will generate asynchronous reset signal to the corresponding module. User needs to set these bits to “0” to release the module from the reset state.

Register	Offset	R/W	Description				Reset Value
IPRSTC2	GCR_BA+0x0C	R/W	Peripheral Reset Control Register 2				0x0000_0000

Bits	Description	
[31:29]	Reserved	Reserved.
[28]	ADC_RST	ADC Controller Reset 0 = ADC controller normal operation. 1 = ADC controller reset.
[27:24]	Reserved	Reserved.
[23]	ACMP23_RST	Analog Comparator B Controller Reset (M05xxDN/DE Only) 0 = Analog Comparator B controller normal operation. 1 = Analog Comparator B controller reset.
[22]	ACMP01_RST	Analog Comparator A Controller Reset 0 = Analog Comparator A controller normal operation. 1 = Analog Comparator A controller reset.
[21]	PWM47_RST	PWM47 Controller Reset 0 = PWM47 controller normal operation. 1 = PWM47 controller reset.
[20]	PWM03_RST	PWM03 Controller Reset 0 = PWM03 controller normal operation. 1 = PWM03 controller reset.
[19:18]	Reserved	Reserved.
[17]	UART1_RST	UART1 Controller Reset 0 = UART1 controller normal operation. 1 = UART1 controller reset.

[16]	UART0_RST	UART0 Controller Reset 0 = UART0 controller normal operation. 1 = UART0 controller reset.
[15:14]	Reserved	Reserved.
[13]	SPI1_RST	SPI1 Controller Reset 0 = SPI1 controller normal operation. 1 = SPI1 controller reset.
[12]	SPI0_RST	SPI0 Controller Reset 0 = SPI0 controller normal operation. 1 = SPI0 controller reset.
[11:10]	Reserved	Reserved.
[9]	I2C1_RST	I²C1 Controller Reset (M05xxDN/DE Only) 0= I ² C1 controller normal operation. 1= I ² C1 controller reset.
[8]	I2C0_RST	I²C Controller Reset 0= I ² C0 controller normal operation. 1= I ² C0 controller reset.
[7:6]	Reserved	Reserved.
[5]	TMR3_RST	Timer3 Controller Reset 0 = Timer3 controller normal operation. 1 = Timer3 controller reset.
[4]	TMR2_RST	Timer2 Controller Reset 0 = Timer2 controller normal operation. 1 = Timer2 controller reset.
[3]	TMR1_RST	Timer1 Controller Reset 0 = Timer1 controller normal operation. 1 = Timer1 controller reset.
[2]	TMR0_RST	Timer0 Controller Reset 0 = Timer0 controller normal operation. 1 = Timer0 controller reset.
[1]	GPIO_RST	GPIO (P0~P4) Controller Reset 0 = GPIO controller normal operation. 1 = GPIO controller reset.
[0]	Reserved	Reserved.

Brown-out Detector Control Register (BODCR)

Partial values of the BODCR control registers are initiated by the flash configuration and partial bits are write-protected. Programming the write-protected bits needs to write “59h”, “16h”, and “88h” to address 0x5000_0100 to disable register protection. Refer to the REGWRPROT register at address GCR_BA+0x100.

Register	Offset	R/W	Description				Reset Value
BODCR	GCR_BA+0x18	R/W	Brown-out Detector Control Register				0x0000_008X

31	30	29	28	27	26	25	24
Reserved							
23	22	21	20	19	18	17	16
Reserved							
15	14	13	12	11	10	9	8
Reserved							
7	6	5	4	3	2	1	0
LVR_EN	BOD_OUT	BOD_LPM	BOD_INTF	BOD_RSTEN	BOD_VL		BOD_EN

Bits	Description	
[31:8]	Reserved	Reserved.
[7]	LVR_EN	Low Voltage Reset Enable Control (Write Protect) The LVR function reset the chip when the input power voltage is lower than LVR circuit setting. LVR function is enabled by default. 0 = Low Voltage Reset function Disabled. 1 = Low Voltage Reset function Enabled – After enabling the bit, the LVR function will be active with 100us delay for LVR output stable (default). Note: This bit is the protected bit, and programming it needs to write “59h”, “16h”, and “88h” to address 0x5000_0100 to disable register protection. Refer to the register REGWRPROT at address GCR_BA+0x100.
[6]	BOD_OUT	Brown-out Detector Output Status 0 = Brown-out Detector output status is 0, which means the detected voltage is higher than BOD_VL setting or BOD_EN is 0. 1 = Brown-out Detector output status is 1, which means the detected voltage is lower than BOD_VL setting. If the BOD_EN is 0, BOD function disabled, this bit always responds to 0.
[5]	BOD_LPM	Brown-out Detector Low Power Mode (Write Protect) 0 = BOD operated in Normal mode (default). 1 = BOD Low Power mode Enabled. Note1: The BOD consumes about 100 uA in Normal mode, and the low power mode can reduce the current to about 1/10 but slow the BOD response. Note2: This bit is the protected bit, and programming it needs to write “59h”, “16h”, and “88h” to address 0x5000_0100 to disable register protection. Refer to the register REGWRPROT at address GCR_BA+0x100.
[4]	BOD_INTF	Brown-out Detector Interrupt Flag 0 = Brown-out Detector does not detect any voltage draft at V _{DD} down through or up through

		the voltage of BOD_VL setting. 1 = When Brown-out Detector detects the V _{DD} is dropped down through the voltage of BOD_VL setting or the V _{DD} is raised up through the voltage of BOD_VL setting, this bit is set to 1 and the Brown-out interrupt is requested if Brown-out interrupt is enabled. Note: Write 1 to clear this bit to 0.															
[3]	BOD_RSTEN	Brown-out Reset Enable Control (Write Protect) 0 = Brown-out "INTERRUPT" function Enabled. While the BOD function is enabled (BOD_EN high) and BOD interrupt function is enabled (BOD_RSTEN low), BOD will assert an interrupt if BOD_OUT is high. BOD interrupt will keep till to the BOD_EN set to 0. BOD interrupt can be blocked by disabling the NVIC BOD interrupt or disabling BOD function (set BOD_EN low). 1 = Brown-out "RESET" function Enabled. Note1: While the Brown-out Detector function is enabled (BOD_EN high) and BOD reset function is enabled (BOD_RSTEN high), BOD will assert a signal to reset chip when the detected voltage is lower than the threshold (BOD_OUT high). Note2: The default value is set by flash controller user configuration register config0 bit[20]. Note3: This bit is the protected bit, and programming it needs to write "59h", "16h", and "88h" to address 0x5000_0100 to disable register protection. Refer to the register REGWRPROT at address GCR_BA+0x100.															
[2:1]	BOD_VL	Brown-out Detector Threshold Voltage Select (Write Protect) The default value is set by flash controller user configuration register config0 bit[22:21] <table border="1"> <thead> <tr> <th>BOV_VL[1]</th> <th>BOV_VL[0]</th> <th>Brown-out voltage</th> </tr> </thead> <tbody> <tr> <td>1</td> <td>1</td> <td>4.4V</td> </tr> <tr> <td>1</td> <td>0</td> <td>3.7V</td> </tr> <tr> <td>0</td> <td>1</td> <td>2.7V</td> </tr> <tr> <td>0</td> <td>0</td> <td>2.2V</td> </tr> </tbody> </table> Note: This bit is the protected bit, and programming it needs to write "59h", "16h", and "88h" to address 0x5000_0100 to disable register protection. Refer to the register REGWRPROT at address GCR_BA+0x100.	BOV_VL[1]	BOV_VL[0]	Brown-out voltage	1	1	4.4V	1	0	3.7V	0	1	2.7V	0	0	2.2V
BOV_VL[1]	BOV_VL[0]	Brown-out voltage															
1	1	4.4V															
1	0	3.7V															
0	1	2.7V															
0	0	2.2V															
[0]	BOD_EN	Brown-out Detector Enable Control (Write Protect) The default value is set by flash controller user configuration register config0 bit[23] 0 = Brown-out Detector function Disabled. 1 = Brown-out Detector function Enabled. Note: This bit is the protected bit, and programming it needs to write "59h", "16h", and "88h" to address 0x5000_0100 to disable register protection. Refer to the register REGWRPROT at address GCR_BA+0x100.															

Temperature Sensor Control Register (TEMPCR)

Register Write-Protection Control Register (REGWRPROT)

Some of the system control registers need to be protected to avoid inadvertent write and disturb the chip operation. These system control registers are protected after the power on reset till user to disable register protection. For user to program these protected registers, a register protection disable sequence needs to be followed by a special programming. The register protection disable sequence is writing the data “59h”, “16h” “88h” to the register REGWRPROT address at 0x5000_0100 continuously. Any different data value, different sequence or any other write to other address during these three data writing will abort the whole sequence.

After the protection is disabled, user can check the protection disable bit at address 0x5000_0100 bit0, “1” is protection disable, “0” is protection enable. Then user can update the target protected register value and then write any data to the address “0x5000_0100” to enable register protection.

Write this register to disable/enable register protection, and reading it to get the REGPROTDIS status.

Register	Offset	R/W	Description					Reset Value

FATCON	0x5000_C018	Flash Access Time Control.
Note: The bits which are write-protected will be noted as " (Write Protect) " beside the description.		

6.2.7 System Timer (SysTick)

The Cortex[®]-M0 includes an integrated system timer, SysTick, which provides a simple, 24-bit clear-on-write, decrementing, wrap-on-zero counter with a flexible control mechanism. The counter can be used as a Real Time Operating System (RTOS) tick timer or as a simple counter.

When system timer is enabled, it will count down from the value in the SysTick Current Value Register (SYST_CVR) to 0, and reload (wrap) to the value in the SysTick Reload Value Register (SYST_RVR) on the next clock cycle, then decrement on subsequent clocks. When the counter transitions to 0, the COUNTFLAG status bit is set. The COUNTFLAG bit clears on reads.

The SYST_CVR value is UNKNOWN on reset. Software should write to the register to clear it to 0 before enabling the feature. This ensures the timer will count from the SYST_RVR value rather than an arbitrary value when it is enabled.

If the SYST_RVR is 0, the timer will be maintained with a current value of 0 after it is reloaded with this value. This mechanism can be used to disable the feature independently from the timer enable bit.

For more detailed information, please refer to the “ARM[®] Cortex[®]-M0 Technical Reference Manual” and “ARM[®] v6-M Architecture Reference Manual”.

6.2.8 System Timer Control Register Map

R: read only, W: write only, R/W: both read and write

Register	Offset	R/W	Description	Reset Value
SYST Base Address:				
SYST_BA = 0xE000_E010				
SYST_CSR	SYST_BA+0x00	R/W	SysTick Control and Status Register	0x0000_0000
SYST_RVR	SYST_BA+0x04	R/W	SysTick Reload Value Register	0xFFFF_FFFF

CURRENT							

Bits	Description	
[31:24]	Reserved	Reserved.
[23:0]	CURRENT	System Tick Current Value Current counter value. This is the value of the counter at the time it is sampled. The counter does not provide read-modify-write protection. The register is write-clear. A software write of any value will clear the register to 0. Unsupported bits RAZ (see SysTick Reload Value register).

6.2.9 Nested Vectored Interrupt Controller (NVIC)

The Cortex[®]-M0 provides an interrupt controller as an integral part of the exception mode, named as “Nested Vectored Interrupt Controller (NVIC)”, which is closely coupled to the processor core and provides following features:

- Nested and Vectored interrupt support
- Automatic processor state saving and restoration
- Reduced and deterministic interrupt latency

The NVIC prioritizes and handles all supported exceptions. All exceptions are handled in “Handler Mode”. This NVIC architecture supports 32 (IRQ[31:0]) discrete interrupts with 4 levels of priority. All of the interrupts and most of the system exceptions can be configured to different priority levels. When an interrupt occurs, the NVIC will compare the priority of the new interrupt to the current running one’s priority. If the priority of the new interrupt is higher than the current one, the new interrupt handler will override the current handler.

When an interrupt is accepted, the starting address of the interrupt service routine (ISR) is fetched from a vector table in memory. There is no need to determine which interrupt is accepted and branch to the starting address of the correlated ISR by software. While the starting address is fetched, NVIC will also automatically save processor state including the registers “PC, PSR, LR, R0~R3, R12” to the stack. At the end of the ISR, the NVIC will restore the mentioned registers from stack and resume the normal execution. Thus it will take less and deterministic time to process the interrupt request.

The NVIC supports “Tail Chaining” which handles back-to-back interrupts efficiently without the overhead of states saving and restoration and therefore reduces delay time in switching to pending ISR at the end of current ISR. The NVIC also supports “Late Arrival” which improves the efficiency of concurrent ISRs. When a higher priority interrupt request occurs before the current ISR starts to execute (at the stage of state saving and starting address fetching), the NVIC will give priority to the higher one without delay penalty. Thus it advances the real-time capability.

For more detailed information, please refer to the “ARM[®] Cortex[®]-M0 Technical Reference Manual” and “ARM[®] v6-M Architecture Reference Manual”.

6.2.9.1 Exception Model and System Interrupt Map

The following table lists the exception model supported by NuMicro[®] M051 series. Software can set four levels of priority on some of these exceptions as well as on all interrupts. The highest user-configurable priority is denoted as “0” and the lowest priority is denoted as “3”. The default priority of all the user-configurable interrupts is “0”. Note that priority “0” is treated as the fourth priority on the system, after three system exceptions “Reset”, “NMI” and “Hard Fault”.

Exception Name	Vector Number	Priority
Reset	1	-3
NMI	2	-2
Hard Fault	3	-1
Reserved	4 ~ 10	Reserved
SVCall	11	Configurable
Reserved	12 ~ 13	Reserved

PendSV	14	Configurable
SysTick	15	Configurable
Interrupt (IRQ0 ~ IRQ31)	16 ~ 47	Configurable

Table 6-2 Exception Model

Exception Number	Vector Address	Interrupt Number (Bit In Interrupt Registers)	Interrupt Name	Source Module	Interrupt Description	Power-Down Wakeup
1-15					System exceptions	
16	0x40	0	BOD_INT	Brown-out	Brown-out low voltage detected interrupt	Yes

Table 6-3 System Interrupt Map Vector Table

6.2.9.2 Vector Table

When an interrupt is accepted, the processor will automatically fetch the starting address of the interrupt service routine (ISR) from a vector table in memory. For ARMv6-M, the vector table base address is fixed at 0x00000000. The vector table contains the initialization value for the stack pointer on reset, and the entry point addresses for all exception handlers. The vector number on previous page defines the order of entries in the vector table associated with exception handler entry as illustrated in previous section.

Vector Table Word Offset	Description
0	SP_main – The Main stack pointer
Vector Number	Exception Entry Pointer using that Vector Number

Table 6-4 Vector Figure Format

6.2.9.3 Operation Description

NVIC interrupts can be enabled and disabled by writing to their corresponding Interrupt Set-Enable or Interrupt Clear-Enable register bit-field. The registers use a write-1-to-enable and write-1-to-clear policy, both registers reading back the current enabled state of the corresponding interrupts. When an interrupt is disabled, interrupt assertion will cause the interrupt to become Pending, however, the interrupt will not be activated. If an interrupt is Active when it is disabled, it remains in its Active state until cleared by reset or an exception return. Clearing the enable bit prevents new activations of the associated interrupt.

NVIC interrupts can be pended/un-pended using a complementary pair of registers to those used to enable/disable the interrupts, named the Set-Pending Register and Clear-Pending Register respectively. The registers use a write-1-to-enable and write-1-to-clear policy, both registers reading back the current pended state of the corresponding interrupts. The Clear-Pending Register has no effect on the execution status of an Active interrupt.

NVIC interrupts are prioritized by updating an 8-bit field within a 32-bit register (each register supporting four interrupts).

The general registers associated with the NVIC are all accessible from a block of memory in the System Control Space and will be described in next section.

6.2.9.4 NVIC Control Register Map

PRI_28		Reserved					

Bits	Description	
[31:30]	PRI_31	Priority of IRQ31 "0" denotes the highest priority and "3" denotes lowest priority.
[23:22]	PRI_30	Priority of IRQ30 "0" denotes the highest priority and "3" denotes lowest priority.
[15:14]	PRI_29	Priority of IRQ29 "0" denotes the highest priority and "3" denotes lowest priority.
[7:6]	PRI_28	Priority of IRQ28 "0" denotes the highest priority and "3" denotes lowest priority.

Interrupt Source Control Registers

Besides the interrupt control registers associated with the NVIC, the NuMicro® M051 series also implements some specific control registers to facilitate the interrupt functions, including “interrupt source identification”, “NMI source selection” and “interrupt test mode”, which are described below.

R: read only, **W:** write only, **R/W:** both read and write

Register	Offset	R/W	Description	Reset Value
INT Base Address:				
INT_BA = 0x5000_0300				
IRQ0_SRC	INT_BA+0x00	R	IRQ0 (BOD) Interrupt Source Identity	0XXXXX_XXXX
IRQ1_SRC	INT_BA+0x04	R	IRQ1 (WDT) Interrupt Source Identity	0XXXXX_XXXX
IRQ2_SRC	INT_BA+0x08	R	IRQ2 (EINT0) Interrupt Source Identity	0XXXXX_XXXX
IRQ3_SRC	INT_BA+0x0C	R	IRQ3 (EINT1) Interrupt Source Identity	0XXXXX_XXXX
IRQ4_SRC	INT_BA+0x10	R	IRQ4 (P0/1) Interrupt Source Identity	0XXXXX_XXXX
IRQ5_SRC	INT_BA+0x14	R	IRQ5 (P2/3/4) Interrupt Source Identity	0XXXXX_XXXX
IRQ6_SRC	INT_BA+0x18	R	IRQ6 (PWMA) Interrupt Source Identity	0XXXXX_XXXX
IRQ7_SRC	INT_BA+0x1C	R	IRQ7 (PWMB) Interrupt Source Identity	0XXXXX_XXXX
IRQ8_SRC	INT_BA+0x20	R	IRQ8 (TMR0) Interrupt Source Identity	0XXXXX_XXXX
IRQ9_SRC	INT_BA+0x24	R	IRQ9 (TMR1) Interrupt Source Identity	0XXXXX_XXXX
IRQ10_SRC	INT_BA+0x28	R	IRQ10 (TMR2) Interrupt Source Identity	0XXXXX_XXXX
IRQ11_SRC	INT_BA+0x2C	R	IRQ11 (TMR3) Interrupt Source Identity	0XXXXX_XXXX

Bits	Description	
[31:9]	Reserved	Reserved.
[8]	NMI_EN	<p>NMI Interrupt Enable Control (Write Protect) 0 = NMI interrupt Disabled. 1 = NMI interrupt Enabled.</p> <p>Note: This bit is the protected bit and programming it needs to write “59h”, “16h”, and “88h” to address 0x5000_0100 to disable register protection. Reference the register REGWRPROT at address GCR_BA+0x100</p>
[7:5]	Reserved	Reserved.
[4:0]	NMI_SEL	<p>NMI Interrupt Source Selection The NMI interrupt to Cortex®-M0 can be selected from one of the peripheral interrupt by setting NMI_SEL.</p>

6.2.10 System Control Block (SCB)

The Cortex®-M0 status and operation mode control are managed by System Control Registers, Including CPUID. Cortex®-M0 interrupt priority and Cortex®-M0 power management can be controlled through these system control registers.

For more detailed information, please refer to the “ARM® Cortex®-M0 Technical Reference Manual” and “ARM® v6-M Architecture Reference Manual”.

6.2.10.1 System Control Block Register Map

R: read only, W: write only, R/W: both read and write

Register	Offset	R/W	Description	Reset Value
SCB Base Address:				
SCB_BA = 0xE000_ED00				
CPUID	SCB_BA+0x000	R	CPUID Register	0x410CC200
ICSR	SCB_BA+0x004	R/W	Interrupt Control State Register	0x0000_0000
AIRCR	SCB_BA+0x00C	R/W	Application Interrupt and Reset Control Register	0xFA05_0000
SCR	SCB_BA+0x010	R/W	System Control Register	0x0000_0000
SHPR2	SCB_BA+0x01C	R/W	System Handler Priority Register 2	0x0000_0000
SHPR3	SCB_BA+0x020	R/W	System Handler Priority Register 3	0x0000_0000

CPUID Base Register (CPUID)

Register	Offset	R/W	Description				Reset Value
CPUID	SCB_BA+0x000	R	CPUID Register				0x410CC200

31	30	29	28	27	26	25	24

15	14	13	12	11	10	9	8
PARTNO							
7	6	5	4	3	2	1	0
PARTNO				REVISION			

Bits	Description	
[31:24]	IMPLEMENTER	Implementer Code Implementer code assigned by ARM. (ARM = 0x41).
[23:20]	Reserved	Reserved.
[19:16]	PART	Architecture of the Processor Read as 0xC for ARMv6-M parts.
[15:4]	PARTNO	Part Number of the Processor Read as 0xC20.
[3:0]	REVISION	Revision Number Read as 0x0.

Interrupt Control State Register (ICSR)

Register	Offset	R/W	Description				Reset Value
ICSR	SCB_BA+0x004	R/W	Interrupt Control State Register				0x0000_0000

31	30	29	28	27	26	25	24
NMIPENDSET	Reserved		PENDSVSET	PENDSVCLR	PENDSTSET	PENDSTCLR	Reserved
23	22	21	20	19	18	17	16
ISRPREEMPT	ISRPENDING	Reserved				VECTPENDING	
15	14	13	12	11	10	9	8
VECTPENDING				Reserved			
7	6	5	4	3	2	1	0
Reserved		VECTACTIVE					

Bits	Description
[31]	<p>NMI Set-pending Bit Write: 0 = No effect. 1 = Changes NMI exception state to pending. Read: 0 = NMI exception not pending. 1 = NMI exception pending. Note: Because NMI is the highest-priority exception, normally the processor enters the NMI exception handler as soon as it detects a write of 1 to this bit. Entering the handler then clears this bit to 0. This means a read of this bit by the NMI exception handler returns 1 only if the NMI signal is reasserted while the processor is executing that handler.</p>
[30:29]	Reserved.
[28]	<p>PendSV Set-pending Bit Write: 0 = No effect. 1 = Changes PendSV exception state to pending. Read: 0 = PendSV exception is not pending. 1 = PendSV exception is pending. Note: Writing 1 to this bit is the only way to set the PendSV exception state to pending</p>
[27]	<p>PendSV Clear-pending Bit Write: 0 = No effect. 1 = Removes the pending state from the PendSV exception. This bit is write-only. To clear the PENDSV bit, you must “write 0 to PENDSVSET and write 1 to PENDSVCLR” at the same time.</p>
[26]	<p>SysTick Exception Set-pending Bit Write:</p>

		0 = No effect. 1 = Changes SysTick exception state to pending. Read: 0 = SysTick exception is not pending. 1 = SysTick exception is pending.
[25]	PENDSTCLR	SysTick Exception Clear-pending Bit Write: 0 = No effect. 1 = Removes the pending state from the SysTick exception. Note: This bit is write-only. When you want to clear PENDST bit, you must “write 0 to PENDSTSET and write 1 to PENDSTCLR” at the same time.
[24]	Reserved	Reserved.
[23]	ISRPREEMPT	Interrupt Preempt Bit If set, a pending exception will be serviced on exit from the debug halt state. This bit is read only.
[22]	ISRPENDING	Interrupt Pending Flag, Excluding NMI and Faults (Read Only) 0 = Interrupt not pending. 1 = Interrupt pending.
[21:18]	Reserved	Reserved.
[17:12]	VECTPENDING	Exception Number of the Highest Priority Pending Enabled Exception 0 = No pending exceptions. Non-zero = Exception number of the highest priority pending enabled exception.
[11:6]	Reserved	Reserved.
[5:0]	VECTACTIVE	Contains the Active Exception Number 0 = Thread mode. Non-zero = Exception number of the currently active exception.

Application Interrupt and Reset Control Register (AIRCR)

Register	Offset	R/W	Description					Reset Value
AIRCR	SCB_BA+0x00C	R/W	Application Interrupt and Reset Control Register					0xFA05_0000

31	30	29	28	27	26	25	24
VECTORKEY							
23	22	21	20	19	18	17	16
VECTORKEY							
15	14	13	12	11	10	9	8
Reserved							
7	6	5	4	3	2	1	0
Reserved					SYSRESETREQ	VECTCLRACTIVE	Reserved

Bits	Description	
[31:16]	VECTORKEY	Register Access Key Write: When writing to this register, the VECTORKEY field need to be set to 0x05FA, otherwise the write operation would be ignored. The VECTORKEY filed is used to prevent accidental write to this register from resetting the system or clearing of the exception status. Read: Read as 0xFA05.
[15:3]	Reserved	Reserved.
[2]	SYSRESETREQ	System Reset Request Writing this bit 1 will cause a reset signal to be asserted to the chip to indicate a reset is requested. The bit is a write only bit and self-clears as part of the reset sequence.
[1]	VECTCLRACTIVE	Exception Active Status Clear Bit Reserved for debug use. When writing to the register, user must write 0 to this bit, otherwise behavior is unpredictable.
[0]	Reserved	Reserved.

System Control Register (SCR)

Register	Offset	R/W	Description				Reset Value
SCR	SCB_BA+0x010	R/W	System Control Register				0x0000_0000

31	30	29	28	27	26	25	24

Bits	Description	
[31:30]	PRI_15	Priority of System Handler 15 – SysTick “0” denotes the highest priority and “3” denotes the lowest priority
[29:24]	Reserved	Reserved.
[23:22]	PRI_14	Priority of System Handler 14 – PendSV “0” denotes the highest priority and “3” denotes the lowest priority
[21:0]	Reserved	Reserved.

6.2.11 Register Protection

Some of the system control registers need to be protected to avoid inadvertent write and disturb the chip operation. These system control registers are protected after the power on reset till user to disable register protection. For user to program these protected registers, a register protection disable sequence needs to be followed by a special programming. The register protection disable sequence is writing the data “59h”, “16h” “88h” to the register REGWRPROT continuously. Any different data value, different sequence or any other write to other address during these three data writing will abort the whole sequence.

After the protection is disabled, user can check REGPROTDIS (REGWRPROT [0]), “1” is protection disable, “0” is protection enable. Then user can update the target protected register value and then write any data to REGWRPROT to enable register protection.

The protected registers are listed as following table.

Register	Bit	Description
IPRSTC1	[4] HDIV_RST	HDIV Controller Reset (Write Protect) (M05xxDN/DE Only)
	[3] EBI_RST	EBI Controller Reset (Write Protect)
	[1] CPU_RST	Cortex-m0 Core One-shot Reset (Write Protect)
	[0] CHIP_RST	Chip One-shot Reset (Write Protect)
BODCR	[7] LVR_EN	Low Voltage Reset Enable Control (Write Protect)
	[5] BOD_LPM	Brown-out Detector Low Power Mode (Write Protect)
	[3] BOD_RSTEN	Brown-out Reset Enable Control (Write Protect)
	[2:1] BOD_VL	Brown-out Detector Threshold Voltage Select (Write Protect)
	[0] BOD_EN	Brown-out Detector Enable Control (Write Protect)
PORCR	[15:0] POR_DIS_CODE	Power-on Reset Enable Control (Write Protect)
NMI_SEL	[8] NMI_EN	NMI Interrupt Enable Control (Write Protect)
PWRCON	[8] PD_WAIT_CPU	Power-down Entry Condition Control (Write Protect)
	[7] PWR_DOWN_EN	System Power-down Enable Bit (Write Protect)
	[5] PD_WU_INT_EN	Power-down Mode Wake-up Interrupt Enable Control (Write Protect)
	[4] PD_WU_DLY	Wake-up Delay Counter Enable Control (Write Protect)
	[3] OSC10K_EN	10 KHz Internal Low Speed RC Oscillator (LIRC) Enable Control (Write Protect)
	[2] OSC22M_EN	22.1184 MHz Internal High Speed RC Oscillator (HIRC) Enable Control (Write Protect)
	[0] XTL12M_EN	4~24 MHz External High Speed Crystal (HXT) Enable Control (Write Protect)
APBCLK	[0] WDT_EN	Watchdog Timer Clock Enable Control (Write Protect)
CLKSEL0	[5:3] STCLK_S	Cortex®-M0 SysTick Clock Source Selection From Reference Clock (Write Protect)
	[2:0] HCLK_S	HCLK Clock Source Selection (Write Protect)
CLKSEL1	[1:0] WDT_S	Watchdog Timer Clock Source Selection (Write Protect)
ISPON	[6] ISPFF	ISP Fail Flag (Write Protect)

	[5] LDUEN	LDROM Update Enable Control (Write Protect)
	[4] CFGUEN	CONFIG Update Enable Control (Write Protect)
	[3] APUEN	APROM Update Enable Control (Write Protect)
	[1] BS	Boot Select (Write Protect)
	[0] ISPEN	ISP Enable Control (Write Protect)
ISPTRG	[0] ISPGO	ISP Start Trigger (Write Protect)
FATCON	[4] LFOM	Low Frequency Optimization Mode Control (Write Protect)
ISPSTA	[6] ISPFF	ISP Fail Flag (Write Protect)
TCSR0 TCSR1 TCSR2 TCSR3	[31] DBGACK_TMR	ICE Debug Mode Acknowledge Disable (Write Protect)
WTCR	[31] DBGACK_WDT	ICE Debug Mode Acknowledge Disable Control (Write Protect)
	[10:8] WTIS	Watchdog Timer Time-out Interval Selection (Write Protect)
	[7] WTE	Watchdog Timer Enable Control (Write Protect)
	[6] WTIE	Watchdog Timer Time-out Interrupt Enable Control (Write Protect)
	[4] WTWKE	Watchdog Timer Time-out Wake-up Function Control (Write Protect)
	[1] WTRE	Watchdog Timer Time-out Reset Enable Control (Write Protect)
	[0] WTR	Reset Watchdog Timer Up Counter (Write Protect)
WTCRALT	[1:0] WTRDSEL	Watchdog Timer Reset Delay Selection (Write Protect)

Table 6-5 Proected Register

6.3 Clock Controller

6.3.1 Overview

The clock controller generates clocks for the whole chip, including system clocks and all peripheral clocks. The clock controller also implements the power control function with the individually clock ON/OFF control, clock source selection and clock divider. The chip enters Power-down mode when Cortex®-M0 core executes the WFI instruction only if the PWR_DOWN_EN (PWRCON[7]) bit and PD_WAIT_CPU (PWRCON[8]) bit are both set to 1. After that, chip enters Power-down mode and waits for wake-up interrupt source triggered to exit Power-down mode. In Power-down mode, the clock controller turns off the 4~24 MHz external high speed crystal (HXT) and 22.1184 MHz internal high speed RC oscillator (HIRC) to reduce the overall system power consumption. The following figures show the clock generator and the overview of the clock source control.

The clock generator consists of 4 clock sources as listed below:

- 4~24 MHz external high speed crystal oscillator (HXT)
- Programmable PLL output clock frequency (PLL source can be selected from external 4~24 MHz external high speed crystal (HXT) or 22.1184 MHz internal high speed oscillator (HIRC)) (PLL FOUT)
- 22.1184 MHz internal high speed RC oscillator (HIRC)
- 10 kHz internal low speed RC oscillator (LIRC)

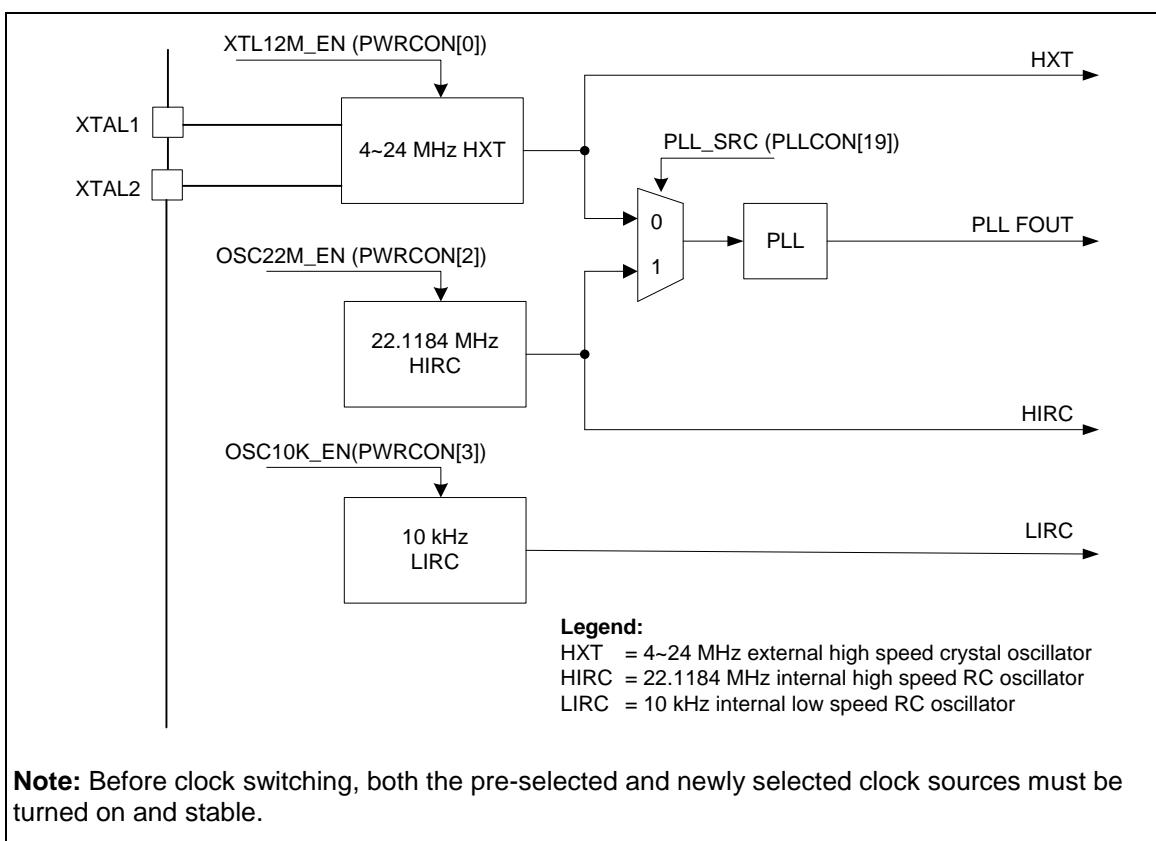

Figure 6-3 Clock Generator Block Diagram

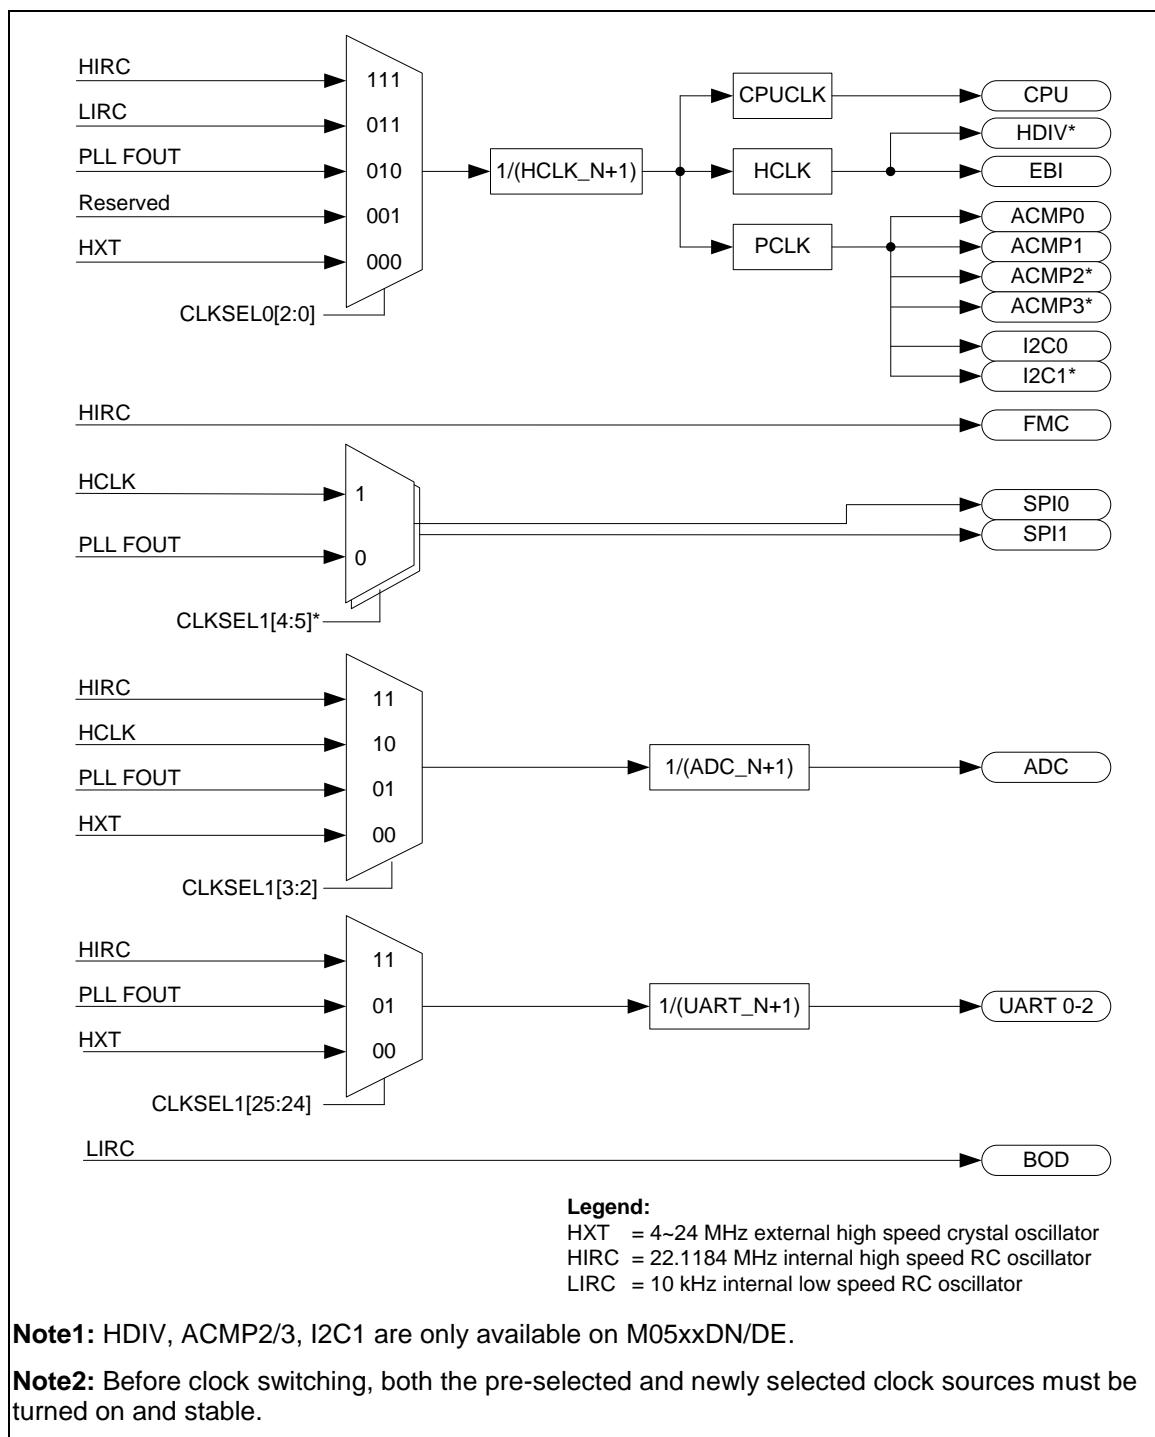

Figure 6-4 Clock Source Controller Overview (1/2)

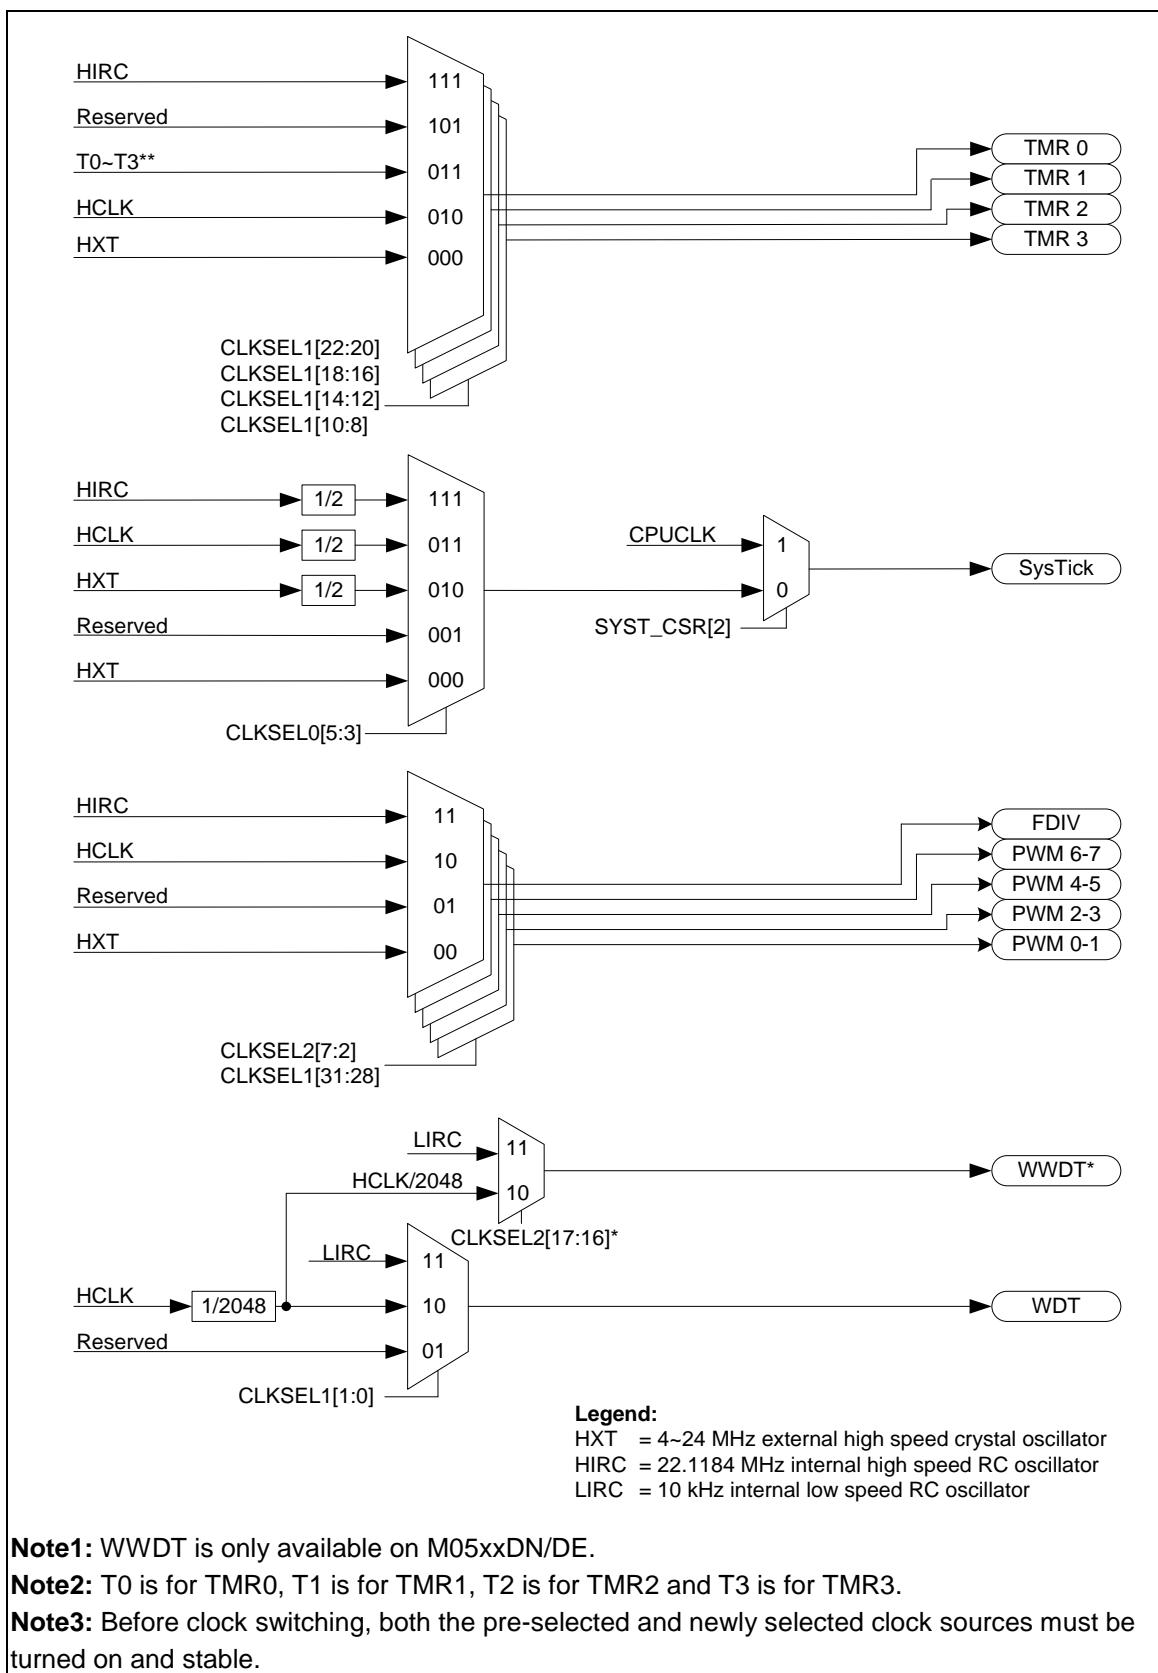

Figure 6-5 Clock Source Controller Overview (2/2)

6.3.2 System Clock and SysTick Clock

The system clock has 4 clock sources which were generated from clock generator block. The clock source switch depends on the register HCLK_S (CLKSEL0[2:0]). The block diagram is shown below.

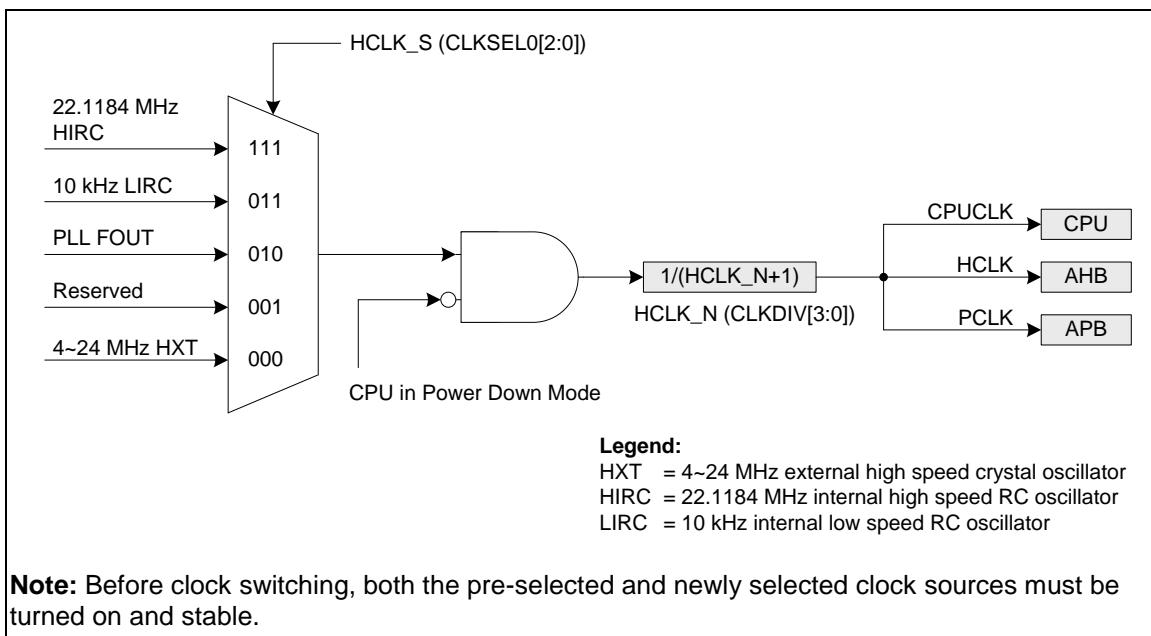

Figure 6-6 System Clock Block Diagram

The clock source of SysTick in Cortex-M0 core can use CPU clock or external clock (SYST_CSR[2]). If using external clock, the SysTick clock (STCLK) has 4 clock sources. The clock source switch depends on the setting of the register STCLK_S (CLKSEL0[5:3]). The block diagram is shown below.

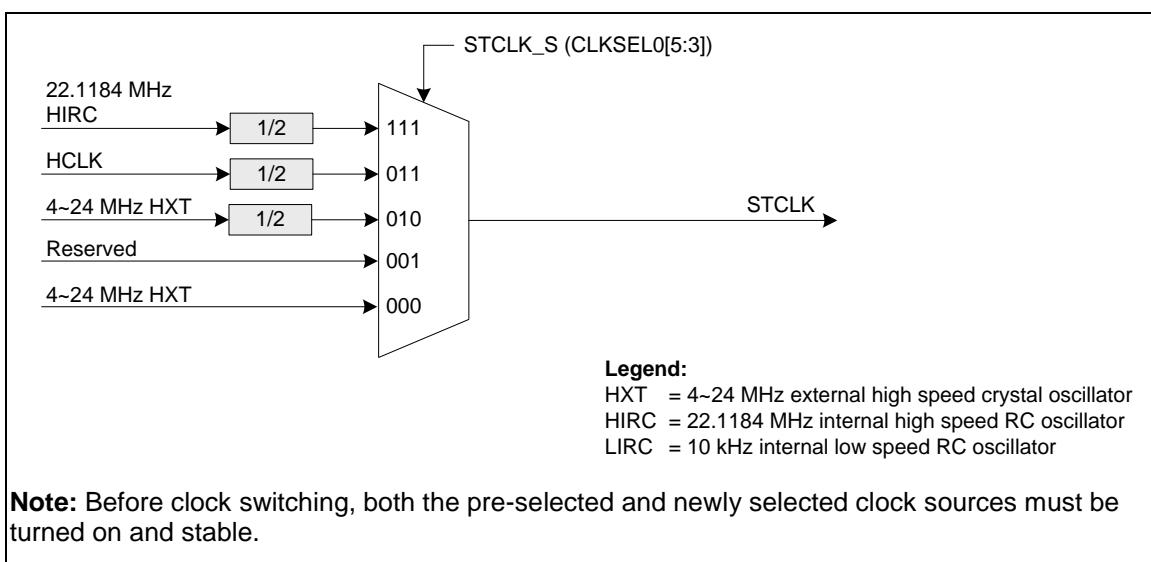

Figure 6-7 SysTick clock Control Block Diagram

6.3.3 Power-down Mode Clock

When chip enters Power-down mode, system clocks, some clock sources, and some peripheral clocks will be disabled. Some clock sources and peripherals clocks are still active in Power-down mode.

The clocks still kept active are listed below:

- Clock Generator
- 10 kHz internal low speed oscillator clock
- Peripherals Clock (when 10 kHz low speed oscillator is adopted as clock source)

6.3.4 Frequency Divider Output

This device is equipped with a power-of-2 frequency divider which is composed by 16 chained divide-by-2 shift registers. One of the 16 shift register outputs selected by a sixteen to one multiplexer is reflected to the CKO pin. Therefore there are 16 options of power-of-2 divided clocks with the frequency from $F_{in}/2^1$ to $F_{in}/2^{16}$ where F_{in} is input clock frequency to the clock divider.

The output formula is $F_{out} = F_{in}/2^{(N+1)}$, where F_{in} is the input clock frequency, F_{out} is the clock divider output frequency and N is the 4-bit value in FSEL (FRQDIV [3:0]).

When writing 1 to DIVIDER_EN (FRQDIV[4]), the chained counter starts to count. When writing 0 to DIVIDER_EN (FRQDIV[4]), the chained counter continuously runs till divided clock reaches low state and stay in low state.

On M05xxDN/DE, if DIVIDER1(FRQDIV[5]) set to 1, the frequency divider clock (FRQDIV_CLK) will bypass power-of-2 frequency divider. The frequency divider clock will be output to CKO pin directly.

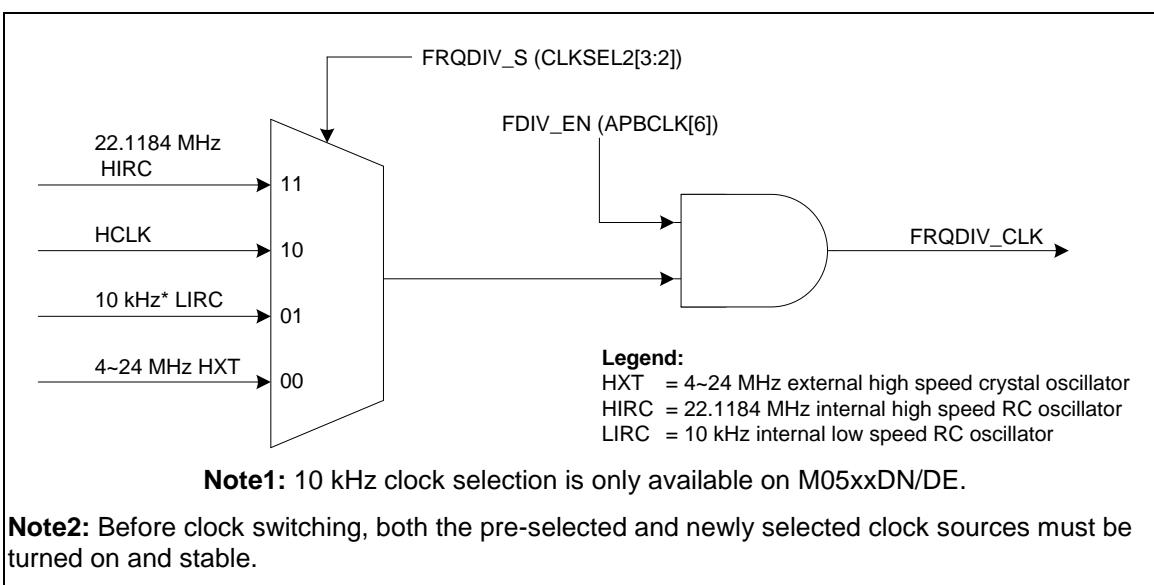

Figure 6-8 Clock Source of Frequency Divider

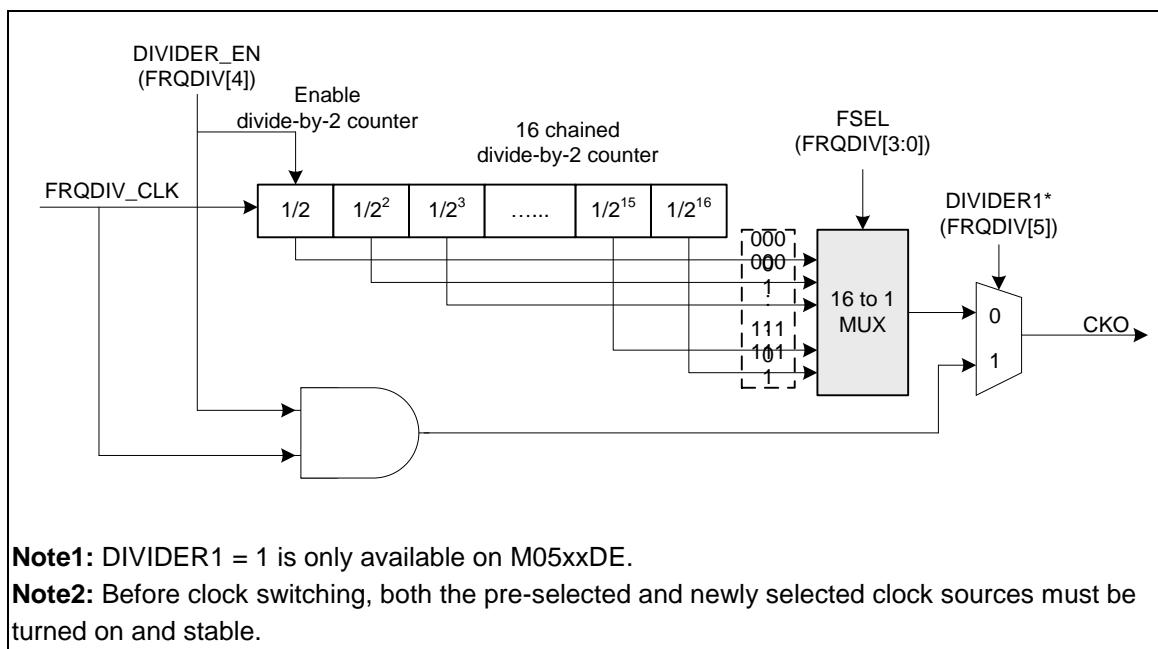

Figure 6-9 Block Diagram of Frequency Divider

6.3.5 Register Map

R: read only, W: write only, R/W: both read and write

Register	Offset	R/W	Description	Reset Value

FRQDIV	CLK_BA+0x24	R/W	Frequency Divider Control Register	0x0000_0000

6.3.6 Register Description

Power-down Control Register (PWRCON)

Except the BIT[6], all the other bits are protected, and programming these bits need to write “59h”, “16h”, “88h” to address 0x5000_0100 to disable register protection. Refer to the REGWRPROT register at address GCR_BA+0x100.

Register	Offset	R/W	Description					Reset Value
PWRCON	CLK_BA+0x00	R/W	System Power-down Control Register					0x0000_001X

31	30	29	28	27	26	25	24
Reserved							
23	22	21	20	19	18	17	16
Reserved							
15	14	13	12	11	10	9	8
Reserved							PD_WAIT_CPU
7	6	5	4	3	2	1	0
PWR_DOWN_EN	PD_WU_STS	PD_WU_INT_EN	PD_WU_DLY	OSC10K_EN	OSC22M_EN	Reserved	XTL12M_EN

Bits	Description	
[31:9]	Reserved	Reserved.
[8]	PD_WAIT_CPU	Power-down Entry Condition Control (Write Protect) 0 = Chip enters Power-down mode when the PWR_DOWN_EN bit is set to 1. 1 = Chip enters Power-down mode when the both PD_WAIT_CPU and PWR_DOWN_EN bits are set to 1 and CPU run WFI instruction.
[7]	PWR_DOWN_EN	System Power-down Enable Bit (Write Protect) When this bit is set to 1, Power-down mode is enabled and chip Power-down behavior will depend on the PD_WAIT_CPU bit (a) If the PD_WAIT_CPU is 0, then the chip enters Power-down mode immediately after the PWR_DOWN_EN bit set. (b) If the PD_WAIT_CPU is 1, then the chip keeps active till CPU run WFI instruction. When chip wakes up from Power-down mode, this bit is cleared by hardware. User needs to set this bit again for next Power-down. In Power-down mode, 4~24 MHz external high speed crystal oscillator (HXT) and the 22.1184 MHz internal high speed oscillator (HIRC) will be disabled in this mode, and 10 kHz internal low speed RC oscillator (LIRC) are not controlled by Power-down mode. In Power-down mode, the PLL and system clock are disabled, and ignored the clock source selection. The clocks of peripheral are not controlled by Power-down mode, if the peripheral clock source is from 10 kHz internal low speed oscillator. 0 = Chip operating normally or chip in Idle mode because of WFI command. 1 = Chip enters Power-down mode instantly or waits CPU sleep command WFI.
[6]	PD_WU_STS	Power-down Mode Wake-up Interrupt Status Set by “Power-down wake-up event”, which indicates that resume from Power-down mode” The flag is set if the GPIO, UART, WDT, ACMP or BOD wake-up occurred.

		Note: This bit works only if PD_WU_INT_EN (PWRCON[5]) set to 1. Write 1 to clear the bit to 0.
[5]	PD_WU_INT_EN	<p>Power-down Mode Wake-up Interrupt Enable Control (Write Protect)</p> <p>0 = Disabled. 1 = Enabled.</p> <p>Note: The interrupt will occur when both PD_WU_STS and PD_WU_INT_EN are high.</p>
[4]	PD_WU_DLY	<p>Wake-up Delay Counter Enable Control (Write Protect)</p> <p>When the chip wakes up from Power-down mode, the clock control will delay certain clock cycles to wait system clock stable.</p> <p>The delayed clock cycle is 4096 clock cycles when chip works at 4~24 MHz external high speed crystal (HXT), and 256 clock cycles when chip works at 22.1184 MHz internal high speed RC oscillator (HIRC).</p> <p>0 = Clock cycles delay Disabled. 1 = Clock cycles delay Enabled.</p>
[3]	OSC10K_EN	<p>10 KHz Internal Low Speed RC Oscillator (LIRC) Enable Control (Write Protect)</p> <p>0 = 10 kHz internal low speed RC oscillator (LIRC) Disabled. 1 = 10 kHz internal low speed RC oscillator (LIRC) Enabled.</p>
[2]	OSC22M_EN	<p>22.1184 MHz Internal High Speed RC Oscillator (HIRC) Enable Control (Write Protect)</p> <p>0 = 22.1184 MHz internal high speed RC oscillator (HIRC) Disabled. 1 = 22.1184 MHz internal high speed RC oscillator (HIRC) Enabled.</p>
[1]	Reserved	Reserved.
[0]	XTL12M_EN	<p>4~24 MHz External High Speed Crystal (HXT) Enable Control (Write Protect)</p> <p>The bit default value is set by flash controller user configuration register config0 [26:24]. When the default clock source is from 4~24 MHz external high speed crystal, this bit is set to 1 automatically.</p> <p>0 = 4 ~ 24 MHz external high speed crystal oscillator (HXT) Disabled. 1 = 4 ~ 24 MHz external high speed crystal oscillator (HXT) Enabled.</p>

Mode	Register Or Instruction	SLEEPDEEP (SCR[2])	PD_WAIT_CPU (PWRCON[8])	PWR_DOWN_EN (PWRCON[7])	CPU Run WFI Instruction	Clock Disable
Normal operation	0	0	0	NO	All clocks disabled by control register	
Idle mode (CPU entering Sleep mode)	0	x	0	YES	Only CPU clock disabled	
Power-down mode (CPU entering Deep Sleep mode)	1	1	1	YES	Most clocks are disabled except 10 kHz and only WDT peripheral clock still enable if its peripheral clock source is selected as 10 kHz.	

Table 6-6 Power-down Mode Control

When chip enters Power-down mode, user can wake-up chip using some interrupt sources. The related interrupt sources and NVIC IRQ enable bits (NVIC_ISER) should be enabled before setting PWR_DOWN_EN bit in PWRCON[7] to ensure chip can enter Power-down and wake-up successfully.

AHB Devices Clock Enable Control Register (AHBCLK)

The bits in this register are used to enable/disable clock for system clock and EBI clock.

Register	Offset	R/W	Description				Reset Value
AHBCLK	CLK_BA+0x04	R/W	AHB Devices Clock Enable Control Register				0x0000_000D

[3:0]	FSEL	Divider Output Frequency Selection The formula of output frequency is: $F_{out} = F_{in}/2^{(N+1)}$. F_{in} is the input clock frequency. F_{out} is the frequency of divider output clock. N is the 4-bit value of FSEL[3:0].

6.4 Flash Memory Controller (FMC)

6.4.1 Overview

The M05xxBN and M05xxDN/DE are equipped with 64/32/16/8 Kbytes on chip embedded Flash memory for application program (APROM) that can be updated through ISP registers. In-System-Programming (ISP) and In-Application-Programming (IAP) enable user to update program memory when chip is soldered on PCB. After chip power on Cortex-M0 CPU fetches code from APROM or LDROM decided by boot select (CBS) in CONFIG0. By the way, the M05xxBN and M05xxDN/DE also provide additional 4 Kbytes DATA Flash for user to store some application depended data before chip power off in 64/32/16/8 Kbytes APROM model.

The M05xxDN/DE provides more settings in CONFIG0 to support more advanced functions, including power-on with tri-state I/O, default to enable WDT after booting, enable WDT in Power-down mode, and IAP functions. The following table shows the added functions of M05xxDN/DE.

	M05xxBN	M05xxDN/DE
CONFIG[6]	Reserved	To support IAP function and Multi-Boot function
CONFIG[10]	Reserved	Select I/O state after booting
CONFIG[30]	Reserved	To support WDT in Power-Down mode when WDT is default on after booting
CONFIG[31]	Reserved	To support WDT default on after booting

Table 6-7 M05xxBN and M05xxDN/DE Function Difference List (FMC)

6.4.2 Features

- Runs up to 50 MHz with zero wait state for continuous address read access
- 64/32/16/8 Kbytes application program memory (APROM)
- 4 Kbytes in system programming (ISP) loader program memory (LDROM)
- Fixed 4 Kbytes Data Flash
- All embedded flash memory supports 512 bytes page erase
- In System Program (ISP)/In Application Program (IAP) to update on chip Flash EPROM

6.4.3 Block Diagram

The flash memory controller consist of AHB slave interface, ISP control logic, writer interface and flash macro interface timing control logic. The block diagram of flash memory controller is shown in the following figure.

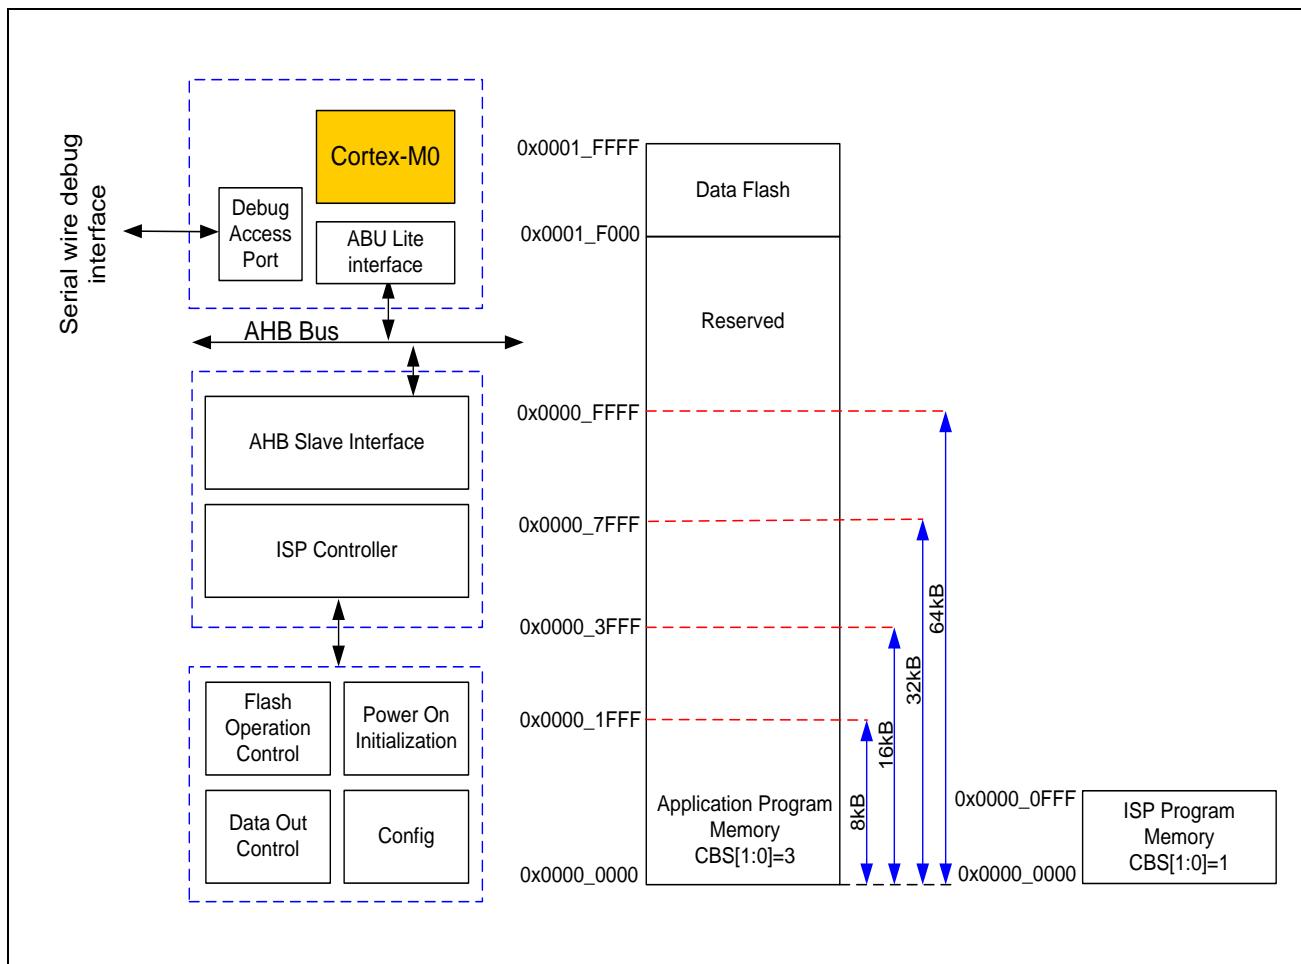

Figure 6-10 Flash Memory Control Block Diagram

6.4.4 FMC Memory Organization

The M05xxBN/DN/DE flash memory consists of program memory (APROM), Data Flash, ISP loader program memory (LDROM), and user configuration.

Program memory is main memory for user applications and called APROM. User can write their application to APROM and set system to boot from APROM.

ISP loader program memory is designed for a loader to implement In-System-Programming function. LDROM is independent to APROM and system can also be set to boot from LDROM. Therefore, user can use LDROM to avoid system boot fail when code of APROM was corrupted.

Data Flash is used for user to store data. It can be read by ISP read or memory read and programmed through ISP register. The size of each erase unit is 512 bytes. Data Flash size is 4 KB and start address is fixed at 0x0001_F000.

User configuration provides several bytes to control system logic, such as flash security lock, boot select, Brown-out voltage level, Data Flash base address, etc.... User configuration works like a fuse for power on setting and loaded from flash memory to its corresponding control register during chip powered on.

In the NuMicro® Family, the flash memory organization is different to system memory map. Flash memory organization is used when user using ISP command to read, program or erase flash memory. System memory map is used when CPU access flash memory to fetch code or data. For example, When system is set to boot from LDROM by CBS[1:0] = 1, CPU will be able to fetch code of LDROM from 0x0 ~ 0xFFFF. However, if user want to read LDROM by ISP, they still need to read the address of LDROM as 0x0010_0000 ~ 0x0010_0FFF.

The following table and figure show the address mapping information of APROM, LDROM, Data Flash and user configuration.

Block Name	Size	Start Address	End Address
AP-ROM	8/16/32/64 Kbytes	0x0000_0000	0x0000_1FFF (8 Kbytes) 0x0000_3FFF (16 Kbytes) 0x0000_7FFF (32 Kbytes) 0x0000_FFFF (64 Kbytes)
Data Flash	4 Kbytes	0x0001_F000	0x0001_FFFF
LD-ROM	4 Kbytes	0x0010_0000	0x0010_0FFF
User Configuration	1 Words	0x0030_0000	0x0030_0000

Table 6-18 Flash Memory Address Map

The Flash memory organization is shown below:

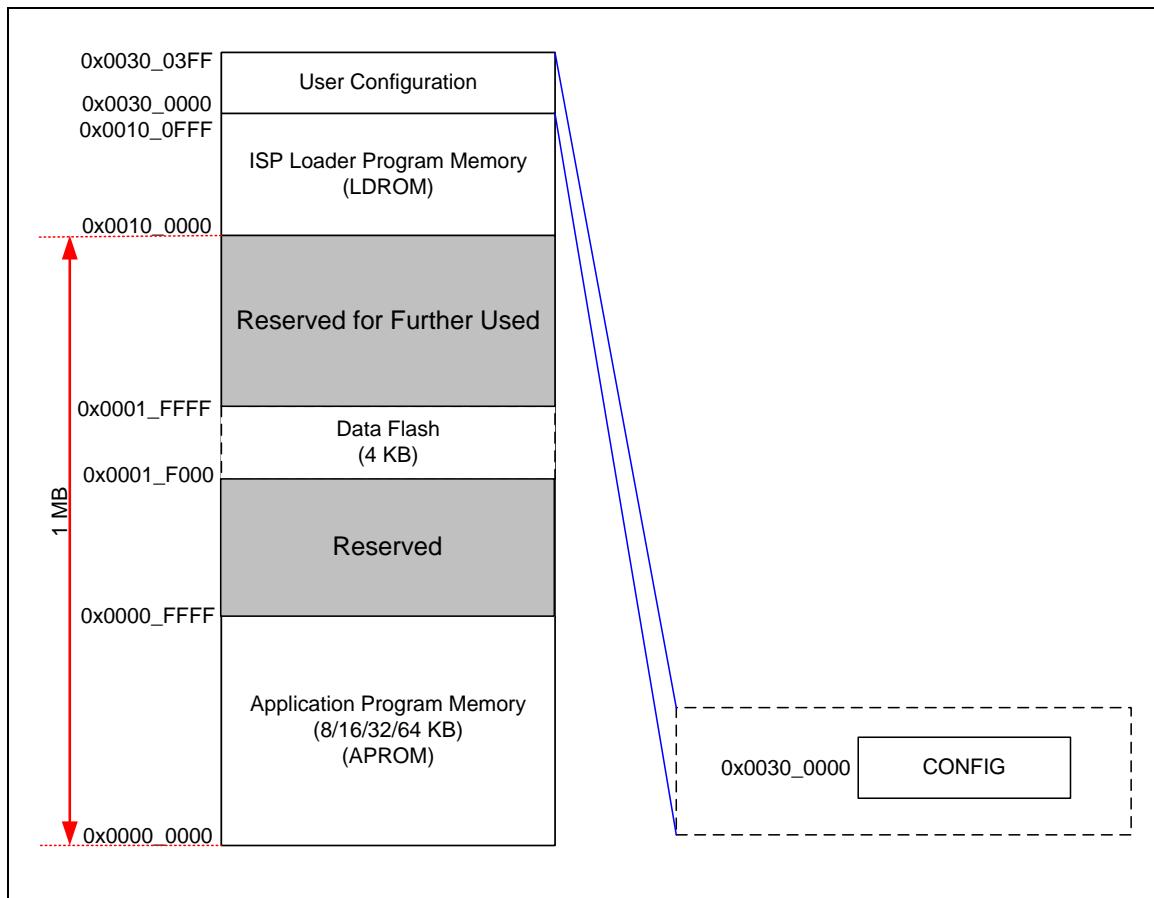

Figure 6-11 Flash Memory Organization

6.4.5 Data Flash

The M05xxBN/DN/DE provides Data Flash for user to store data. It is read/write thru ISP registers. The erase unit is 512 bytes. When a word will be changed, all 128 words need to be copied to another page or SRAM in advance. For 8/16/32/64 Kbytes flash memory device, Data Flash size is 4 Kbytes and start address is fixed at 0x0001_F000.

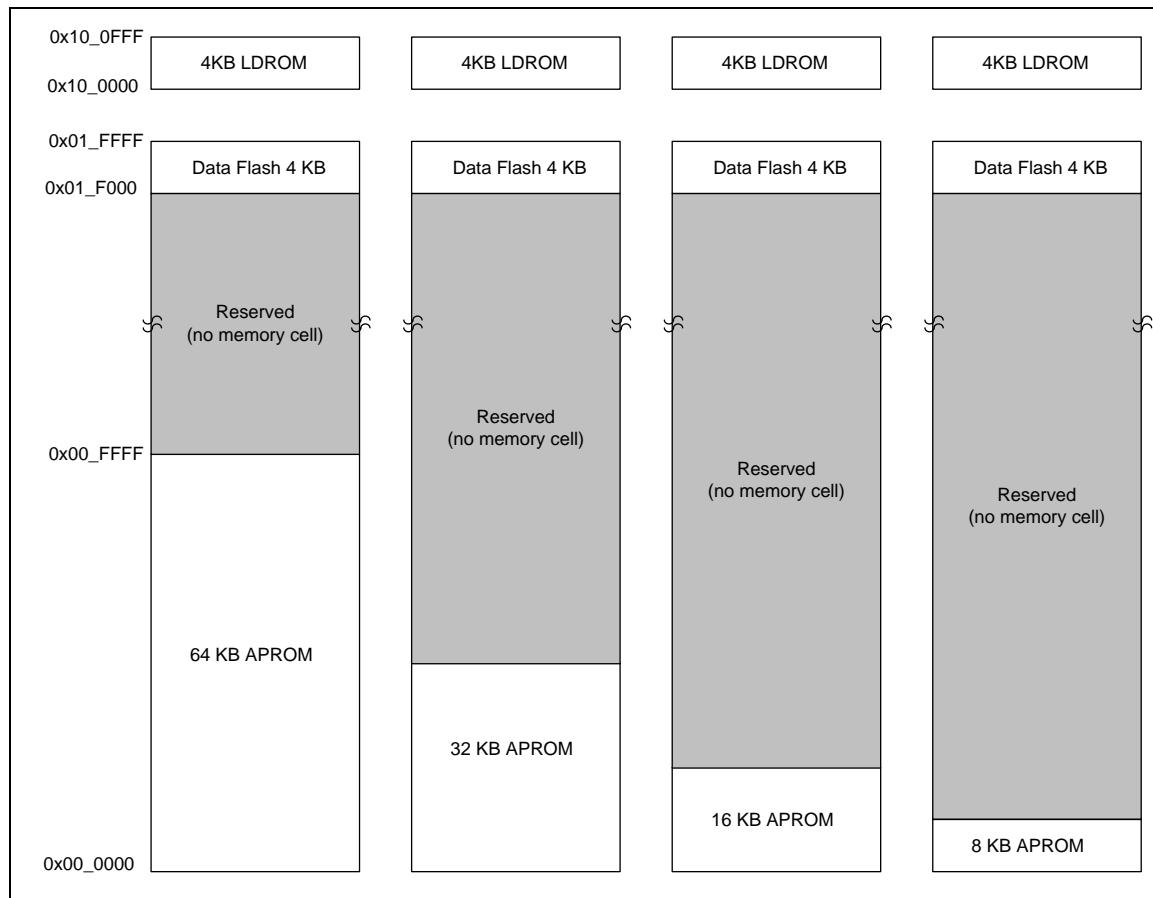

Figure 6-12 Flash Memory Structure

6.4.6 User Configuration

6.4.6.1 Boot options

User configuration is internal programmable configuration area for boot options. The user configuration is located at 0x300000 of Flash Memory Organization and it is 32 bits word. Any change on user configuration will take effect after system reboot.

10	3.7V								
01	2.7V								
00	2.2V								
[20]	CBORST	Brown-out Reset Enable Control 0 = Brown-out reset Enabled after powered on. 1 = Brown-out reset Disabled after powered on.							
[19:11]	Reserved	Reserved.							
[10]	CIOINI	I/O Initial State Selection (M05xxDN/DE Only) 0 = All GPIO default to be input tri-state mode after powered on. 1 = All GPIO default to be Quasi-bidirectional mode after chip is powered on.							
[9:8]	Reserved	Reserved.							
[7:6]	CBS	Chip Boot Selection 00 = LDROM with IAP function. 01 = LDROM without IAP function. 10 = APROM with IAP function. 11 = APROM without IAP function. The M05xxBN only supports CBS[0] = 1, which means no IAP function is supported in M05xxBN. For M05xxDN/DE, user can set CBS[0] = 0 to support IAP function supported. When CBS[0] = 0, the LDROM is mapping to address 0x100000 and APROM is mapping to address 0x0. User could access them by their address without boot switching. In other words, if IAP function is supported, the code in LDROM and APROM can be called by each other. Note1: BS bit of ISPCON is only can be used to control boot switching when CBS[0] = 1. Note2: VECMAP is only can be used to remap to 0x0~0x1ff when CBS[0] = 0.							
[5:2]	Reserved	Reserved.							
[1]	LOCK	Security Lock Control 0 = Flash data is locked 1 = Flash data is not locked. When flash data is locked, only device ID, unique ID, user configuration can be read by writer and ICP through serial debug interface. Others data is locked as 0xFFFFFFFF. ISP can read data anywhere regardless of LOCK bit value. To unlock system, user can use ISP command to disable LOCK bit or erase whole chip (Chip Erase) by ICP tool.							
[0]	Reserved	Reserved.							

Note: The reserved bits of user configuration should be kept as '1'.

6.4.6.2 Brown-out Detection

The M05xxBN and M05xxDN/DE include brown-out detection function for monitoring the voltage on V_{DD} pin. If V_{DD} voltage falls below level setting of CBOV, the BOD event will be triggered when BOD enabled. User can decide to use BOD reset by enable CBORST or just enable BOD interrupt by NVIC when BOD detected. Because BOD reset is issued whenever V_{DD} voltage falls below the level setting of CBOV, user must make sure the CBOV setting to avoid BOD reset right after BOD reset enabled. For example, if the V_{DD} is 3.3V, CBOV could only be 00'b or 01'b. Otherwise, the system will be halted in BOD reset state when BOD reset is enabled and CBOV is 10'b or 11'b.

6.4.7 Boot Selection

The M05xxBN/DN/DE provides in system programming (ISP) feature to support to update program memory when chip is mounted on PCB. A dedicated 4 Kbytes program memory is used to store ISP firmware. Users can select to start program fetch from APROM or LDROM by (CBS) in CONFIG0.

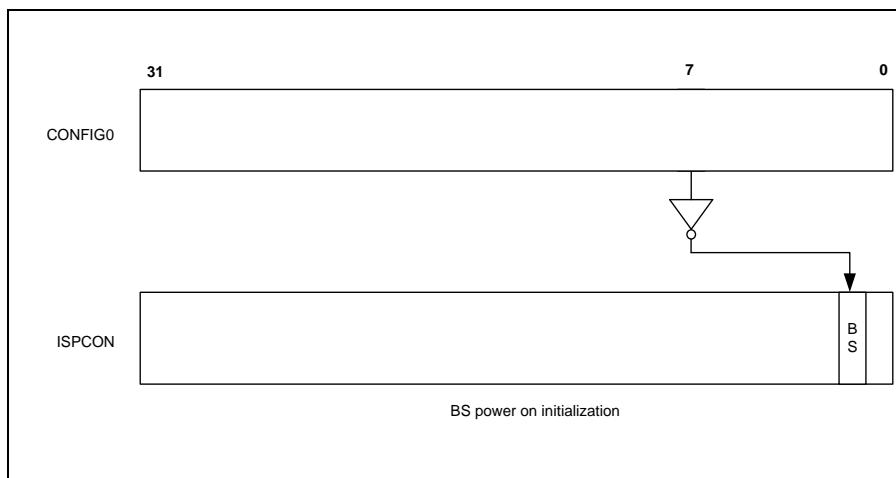

Figure 6-13 Boot Select (BS) for Power-on Action

In addition to setting boot from APROM or LDROM, CBS in CONFIG0 is also used to control system memory map after booting. When CBS[0] = 1 and set CBS[1] = 1 to boot from APROM, the application in APROM will not be able to access LDROM by CPU read. In other words, when CBS[0] = 1 and CBS[1] = 0 are set to boot from LDROM, the software executed in LDROM will not be able to access APROM by memory read. The following figure shows the memory map when booting from APROM and LDROM.

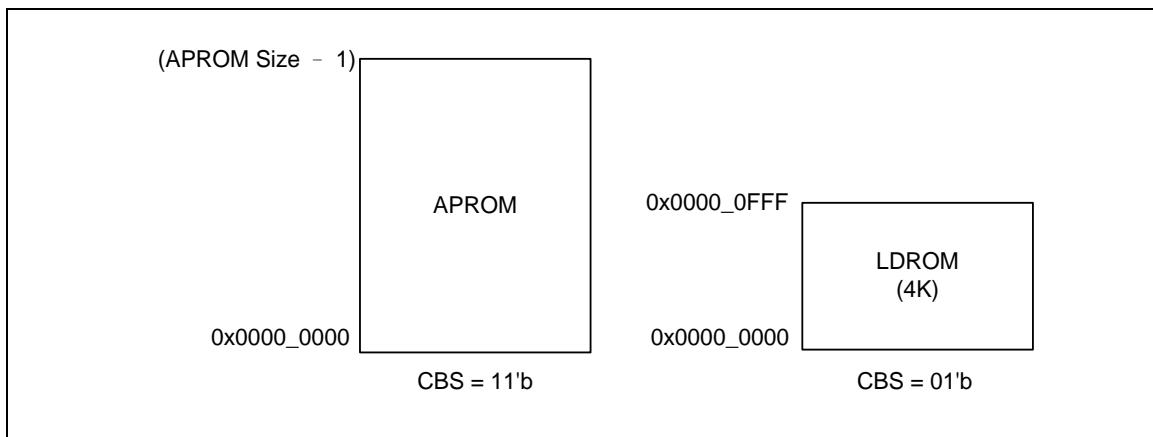

Figure 6-14 Program Executing Range for Booting from APROM and LDROM

For the application that software needs to execute code in APROM and call the functions in LDROM or to execute code in LDROM and call the APROM function without changing boot mode, CBS[0] needs to be set as 0 and this is called In-Application-Programming (IAP). Only M05xxDN/DE supports IAP function.

CBS[1:0]	Boot Selection
00	LDROM with IAP function (M05xxDN/DE Only) Chip booting from LDROM, program executing range including LDROM and most of APROM (all except first 512 bytes as the first 512 bytes is mapped from LDROM). LDROM address is mapping to 0x0010_0000 ~ 0x0010_0FFF , and also the first 512 bytes of LDROM is mapping to the address 0x0000_0000 ~ 0x0000_01FF . The address 0x0000_0000 ~ 0x0000_01FF can be re-mapping to any other page within executing range though ISP command.
01	LDROM without IAP function Chip booting from LDROM, program executing range only including LDROM; APROM cannot be access by program directly, except by through ISP. LDROM is write-protected in this mode.
10	APROM with IAP function (M05xxDN/DE Only) Chip booting from APROM, program executing range including LDROM and APROM LDROM address is mapping to 0x0010_0000~0x0010_0FFF The address 0x0000_0000 ~ 0x0000_01FF can be re-mapping to any other page within executing range though ISP command.
11	APROM without IAP function Chip booting from APROM and program executing range only including APROM. LDROM cannot be access by program directly, except by through ISP. APROM is write-protected in this mode.

Table 6-8 Supported Boot Selection Options

6.4.8 In-Application-Programming (IAP)

The M05xxDN/DE provides In-application-programming (IAP) function for user to switch the code executing between APROM and LDROM without reset. User can enable the IAP function by re-booting chip and setting the chip boot selection bits in CONFIG0 (CBS[1:0]) as 2 or 0.

In the case that the chip boots from APROM with the IAP function enabled (CBS[1:0] = 2), the

executable range of code includes all of APROM and LDROM. The address space of APROM is kept as the original size but the address space of the 4 KB LDROM is mapped to 0x0010_0000~0x0010_0FFF.

In the case that the chip boots from LDROM with the IAP function enabled (CBS[1:0] = 0), the executable range of code includes all of LDROM and almost all of APROM except for its first page. User cannot access the first page of APROM because the first page of executable code range becomes the mirror of the first page of LDROM as set by default. Meanwhile, the address space of 4 KB LDROM is mapped to 0x0010_0000~0x0010_0FFF.

Please refer to following figure for the address map while IAP is activating.

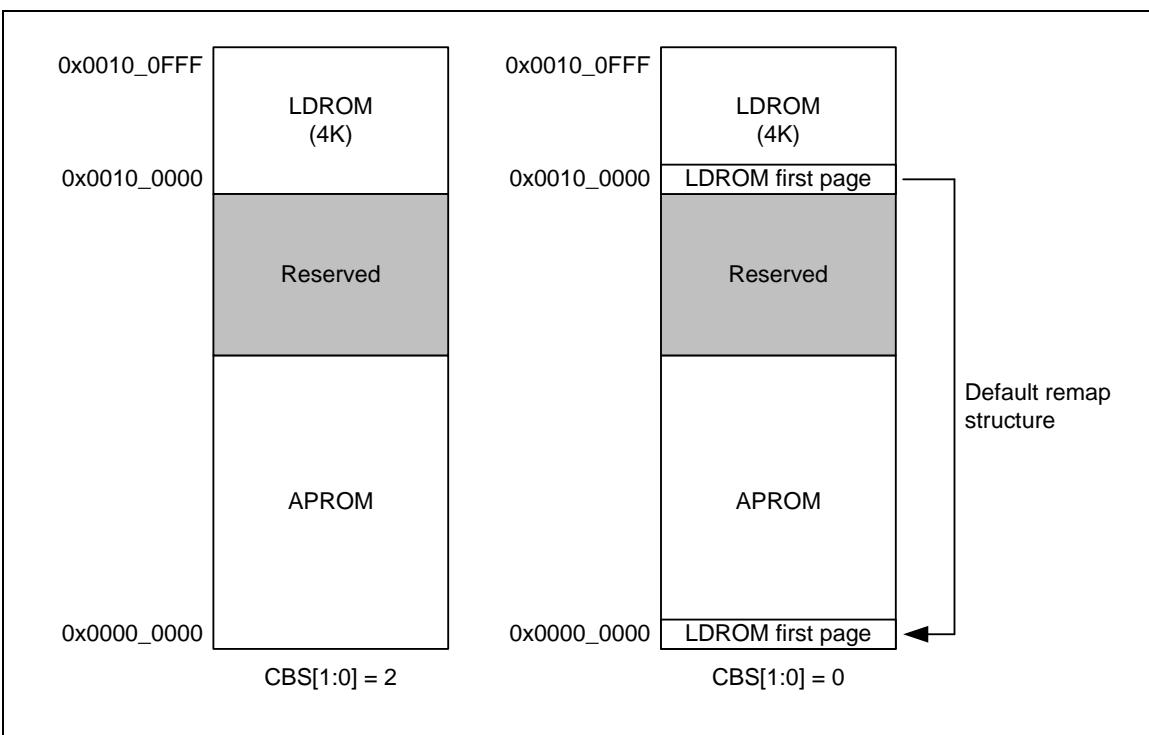

Figure 6-15 Executable Range of Code with IAP Function Enabled

When chip boots with the IAP function enabled, any other page within the executable range of code can be mirrored to the first page of executable code (0x0000_0000~0x0000_01FF) any time. User can change the remap address of the first executing page by filling the target remap address to ISPADR and then go through ISP register with the Vector Page Re-map command. After changing the remap address, user can check if the change is successful by reading the VECMAP field in the ISPSTA register.

6.4.9 In-System-Programming (ISP)

The M05xxBN/DN/DE supports In-System-Programming which allows a device to be reprogrammed under software control and avoids system fail risk when download or programming fail. Furthermore, the capability to update the application firmware makes a wide range of applications possible.

To supports In-System-Programming, M05xxBN/DN/DE includes LDROM and ISP controller. User can implement their ISP loader programming in LDROM and this loader can programming user application code (APROM) through ISP register. In other words, the loader could provide the

ability to update system firmware on board. By ISP loader, various hardware peripheral interfaces make it be easier to receive new program code. The most common method to perform ISP is via UART along with the ISP loader in LDROM. General speaking, PC transfers the new APROM code through serial port. Then ISP loader receives it and reprograms into APROM through ISP commands.

6.4.10 ISP Registers Control Procedure

The M05xxBN/DN/DE supports booting from APROM or LDROM initially defined by user configuration. The change of user configuration needs to reboot system to make it take effect. If user wants to switch between APROM or LDROM mode without changing user configuration with CBS[0] = 1, he needs to control BS bit of ISPCON control register, then reset CPU by IPRSTC1 control register. The boot switching flow by BS bit is shown in the following figure. Boot switching function by BS bit is only valid when CBS[0] = 1.

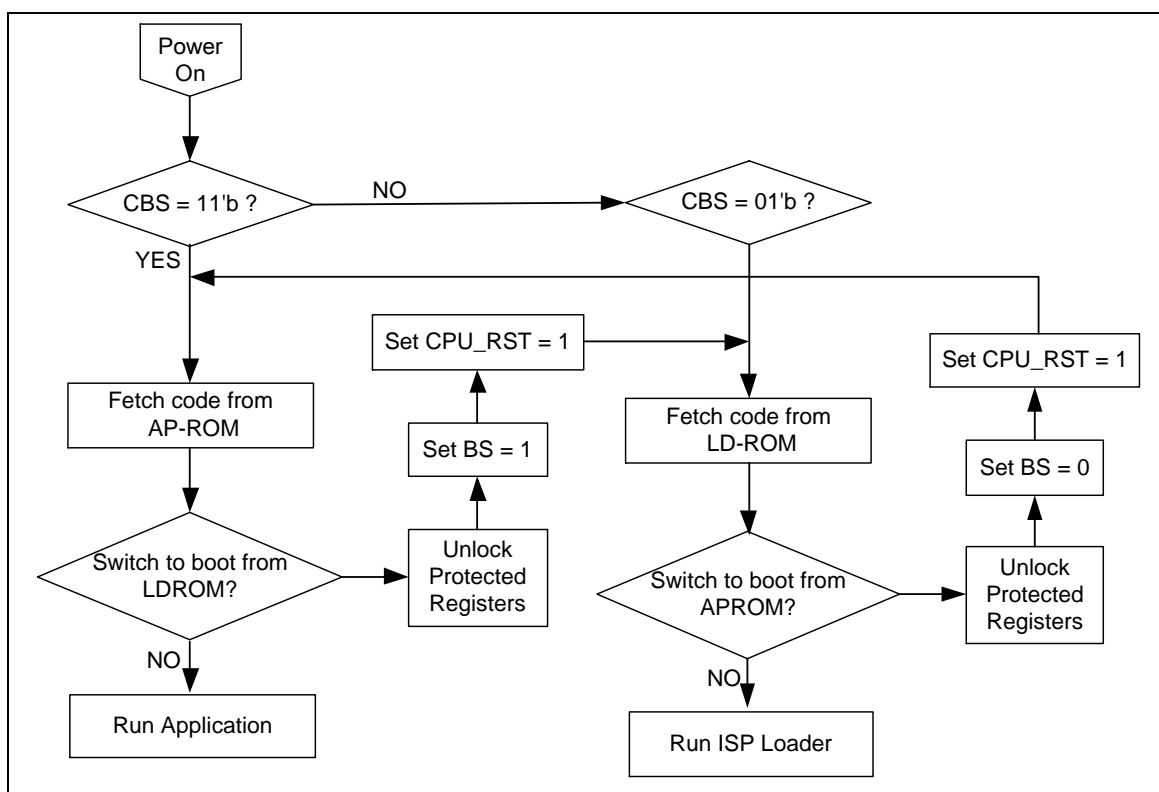

Figure 6-16 Example Flow of Boot Selection by BS Bit when CBS[0] = 1

Updating APROM by software in LDROM or updating LDROM by software in APROM can avoid a system failure when update fails.

The ISP controller supports to read, erase and program embedded flash memory. Several control bits of ISP controller are write-protected, thus it is necessary to unlock before we can set them. To unlock the protected register bits, software needs to write 0x59, 0x16 and 0x88 sequentially to REGWRPROT. If register is unlocked successfully, the value of REGWRPROT will be 1. The unlock sequence must not be interrupted by other access; otherwise it may fail to unlock.

After unlocking the protected register bits, user needs to set the ISPCON control register to

decide to update LDROM, User Configuration, APROM and enable ISP controller.

Once the ISPCON register is set properly, user can set ISPCMD for erase, read or programming. Set ISPADR for target flash memory based on flash memory origination. ISPDAT can be used to set the data to program or used to return the read data according to ISPCMD.

Finally, set ISPGO bit of ISPTRG control register to perform the relative ISP register function. The ISPGO bit is self-cleared when ISP register function has been done. To make sure ISP register function has been finished before CPU goes ahead, ISB instruction is used right after ISPGO setting.

Several error conditions are checked after ISP register function is completed. If an error condition occurs, ISP register operation is not started and the ISP fail flag will be set instead. ISPFF flag can only be cleared by software. The next ISP register control procedure can be started even ISPFF bit is kept as 1. Therefore, it is recommended to check the ISPFF bit and clear it after each ISP register operation if it is set to 1.

When the ISPGO bit is set, CPU will wait for ISP operation to finish during this period; the peripheral still keeps working as usual. If any interrupt request occurs, CPU will not service it till ISP operation is finished. When ISP operation is finished, the ISPGO bit will be cleared by hardware automatically. User can check whether ISP operation is finished or not by the ISPGO bit. User should add ISB instruction next to the instruction in which the ISPGO bit is set 1 to ensure correct execution of the instructions following ISP operation.

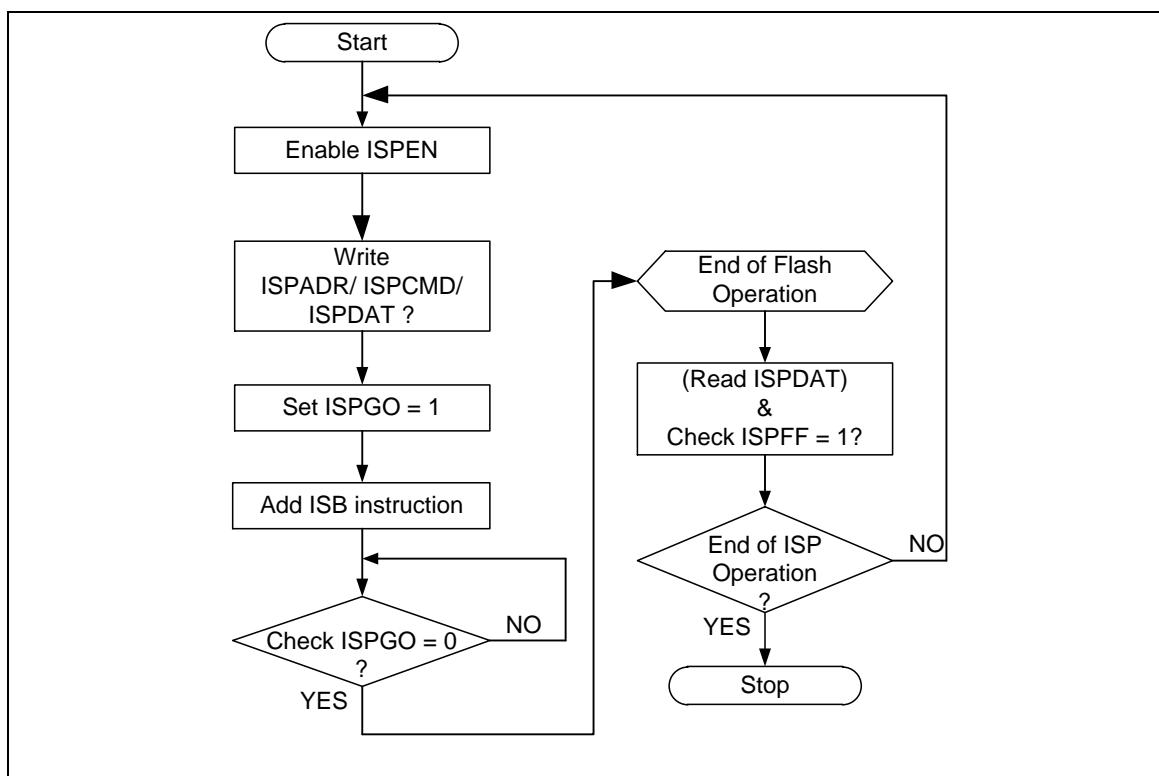

Figure 6-17 ISP Flow Example

The following table lists ISP commands supported by M05xxBN/DN/DE.

Note: The Vector Page Re-Map command is only available on M05xxDN/DE.

ISP Command	ISPCMD	ISPADR	ISPDAT
FLASH Page Erase	0x22	Valid address of flash memory origination. It must be 512 bytes page alignment.	Don't care
FLASH Program	0x21	Valid address of flash memory origination	Programming Data
FLASH Read	0x00	Valid address of flash memory origination	Return Data
Read Unique ID	0x04	0x0000_0000	Unique ID Word 0
		0x0000_0004	Unique ID Word 1
		0x0000_0008	Unique ID Word 2
Read Company ID	0x0B	Don't care	Company ID (0xDA)
Vector Page Re-Map	0x2E	Page in APROM or LDROM It must be 512 bytes page alignment	Don't care

Table 6-9 ISP Command List

6.4.11 Multi-booting by Vector Remapping

The M05xxDN/DE can support to boot from different address by vector page remapping function. When CBS[0] = 0, All pages of LDROM and APROM can be remap to vector address 0x0. The remapping address can be got by VECMAP of ISPSTA register. When CBS[1:0] = 2, the remapping address is default to 0x0 when powered on. This means the vector page is mapping from first page of APROM to boot from APROM at power on. When CBS[1:0] = 0, the remapping address is 0x100000. This means the vector page is mapping from first page of LDROM to boot from LDROM at power on.

The remapping address can be changed by Vector Page Re-Map command. User may remap specified page to vector page by Vector Page Re-Map command, than using CPU_RST or SYSRESETREQ to reset system to reboot. The CPU will fetch the stack and reset handler pointer from new vector page, than boot to the specified application.

For example, if user has two independent applications in APROM called App0 and App1. App0 is located at 0x0, and App1 is located at 0x8000. The CBS[1:0] was set to 0 to boot from LDROM. When power on, the system will execute the code in LDROM. The code in LDROM will decide to boot to App0 or App1. For boot to App0, the code in LDROM will enable ISP and set vector page remapping to 0x0, than reset CPU by CPU_RST(Not reset I/O and peripherals) or SYSRESETREQ(Reset I/O and peripherals) to boot to App0. For boot to App1, the code in LDROM will enable ISP and set vector page remapping to 0x8000, than reset CPU by CPU_RST or SYSRESETREQ to boot to App1. The following figure shows how to use vector page remapping to boot to different applications.

To set vector page remapping, user needs to set new page address to ISPADR, set remap command code 0x2E to ISPCMD. Than trigger ISP command by set ISPGO to 1. User can confirm the new vector page mapping address by ISPSTA control register.

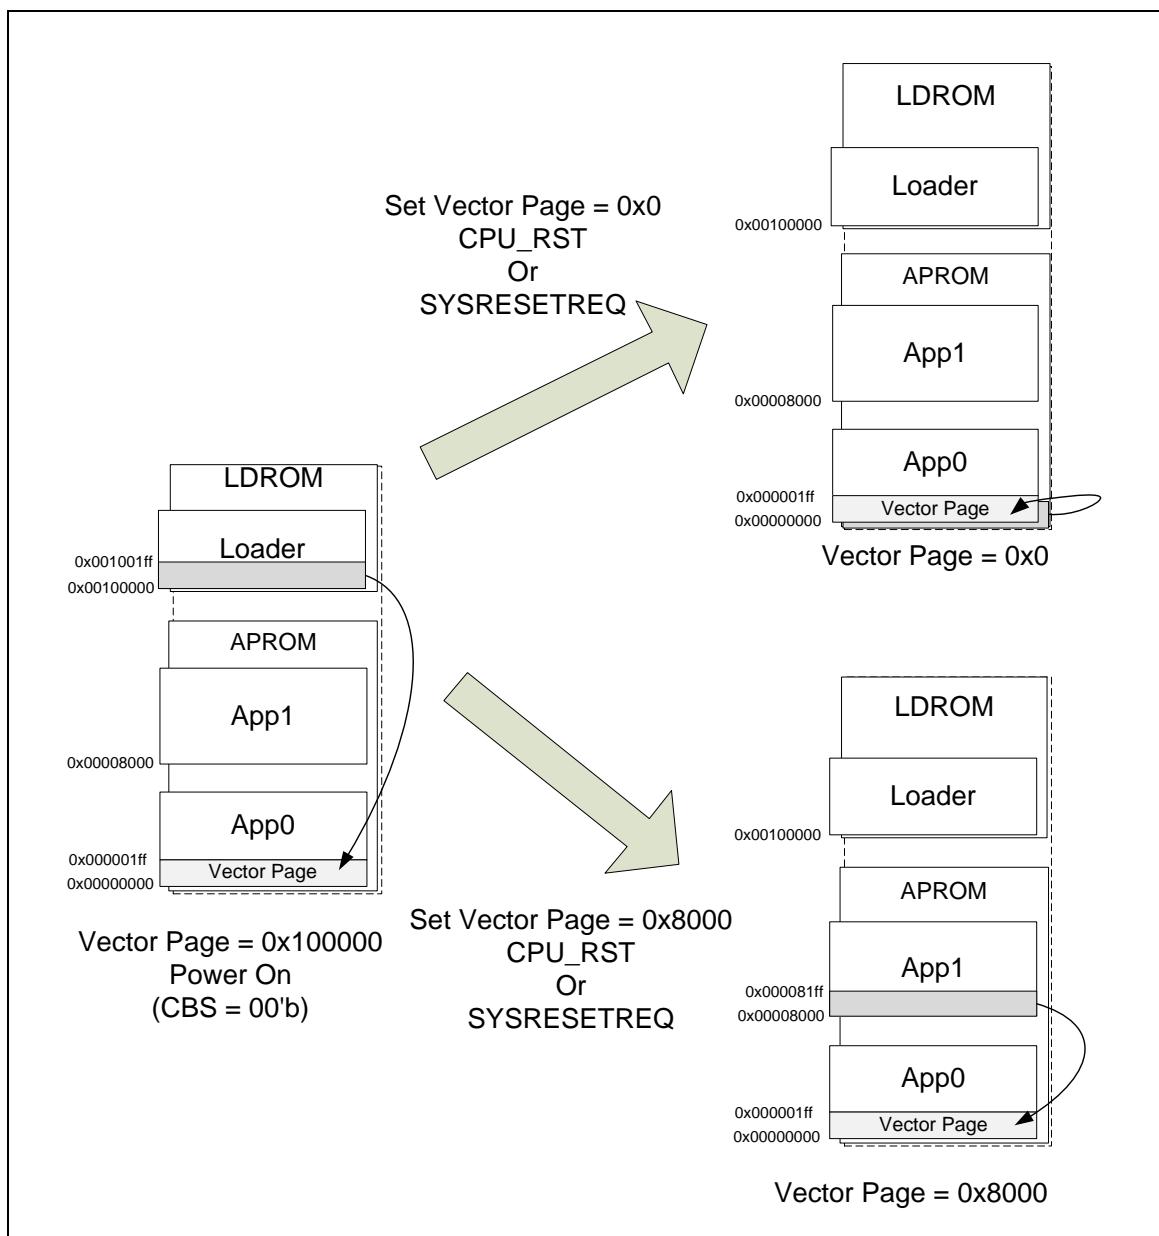

Figure 6-18 Multi-booting by Vector Page Remapping

6.4.12 Register Map

R: read only, W: write only, R/W: both read and write

Register	Offset	R/W	Description	Reset Value
FMC Base Address:				
FMC_BA = 0x5000_C000				
ISPCON	FMC_BA+0x00	R/W	ISP Control Register	0x0000_0000
ISPADR	FMC_BA+0x04	R/W	ISP Address Register	0x0000_0000
ISPDAT	FMC_BA+0x08	R/W	ISP Data Register	0x0000_0000

Reserved							
7	6	5	4	3	2	1	0
Reserved	ISPFF	LDUEN	CFGUEN	APUEN	Reserved	BS	ISPEN

Bits	Description	
[31:7]	Reserved	Reserved.
[6]	ISPFF	ISP Fail Flag (Write Protect) This bit is set by hardware when a triggered ISP meets any of the following conditions: (1) APROM writes to itself if APUEN is set to 0. (2) LDROM writes to itself. (3) Destination address is illegal, such as over an available range. Note: Write 1 to clear this bit to 0.
[5]	LDUEN	LDROM Update Enable Control (Write Protect) 0 = LDROM cannot be updated. 1 = LDROM can be updated when the MCU runs in APROM.
[4]	CFGUEN	CONFIG Update Enable Control (Write Protect) Writing this bit to 1 enables software to update CONFIG value by ISP register control procedure regardless of program code is running in APROM or LDROM. 0 = ISP update User Configuration Disabled. 1 = ISP update User Configuration Enabled.
[3]	APUEN	APROM Update Enable Control (Write Protect) 0 = APROM cannot be updated when chip runs in APROM. 1 = APROM can be updated when chip runs in APROM.
[2]	Reserved	Reserved.
[1]	BS	Boot Select (Write Protect) Set/clear this bit to select next booting from LDROM/APROM, respectively. This bit also functions as chip booting status flag, which can be used to check where chip booted from. This bit is initiated with the inversed value of CBS in CONFIG0 after any reset is happened except CPU reset (RSTS_CPU is 1) or system reset (RSTS_SYS) is happened. 0 = Boot from APROM. 1 = Boot from LDROM.

[0]	ISPEN	ISP Enable Control (Write Protect) Set this bit to enable ISP function. 0 = ISP function Disabled. 1 = ISP function Enabled.
-----	--------------	--

ISP Address Register (ISPADR)

Register	Offset	R/W	Description					Reset Value
ISPADR	FMC_BA+0x04	R/W	ISP Address Register					0x0000_0000

Bits	Description	
[31:21]	Reserved	Reserved.
[20:9]	VECMAP	Vector Page Mapping Address (Read Only) The current flash address space 0x0000_0000~0x0000_01FF is mapping to address {VECMAP[11:0], 9'h000} ~ {VECMAP[11:0], 9'h1FF}
[8:7]	Reserved	Reserved.
[6]	ISPFF	ISP Fail Flag (Write Protect) This bit is set by hardware when a triggered ISP meets any of the following conditions: (1) APROM writes to itself (2) LDROM writes to itself (3) CONFIG is erased/programmed if CFGUEN is set to 0 (4) Destination address is illegal, such as over an available range Write 1 to clear this bit. Note: The function of this bit is the same as ISPCON bit 6
[5:3]	Reserved	Reserved.
[2:1]	CBS	Chip Boot Select (Read Only) This is a mirror of CBS in CONFIG0.
[0]	ISPGO	ISP Start Trigger (Read Only) Write 1 to start ISP operation and this bit will be cleared to 0 by hardware automatically when ISP operation is finished. 0 = ISP operation is finished. 1 = ISP operation is progressed. Note: This bit is the same as ISPTRG bit0

6.5 External Bus Interface (EBI)

6.5.1 Overview

The NuMicro® M05xxBN/DN/DE LQFP-48 package has an external bus interface (EBI) for access external device.

To save the connections between external device and this chip, EBI supports address bus and data bus multiplex mode which is differentiated by address latch enable signal.

6.5.2 Features

The External Bus Interface has the following functions:

- Supports external devices with max. 64 KB size (8-bit data width) / 128 KB (16-bit data width)
- Supports variable external bus base clock (MCLK) which based on HCLK
- Supports 8-bit or 16-bit data width
- Supports variable data access time (tACC), address latch enable time (tALE) and address hold time (tAHD)
- Supports address bus and data bus multiplex mode to save the address pins
- Supports configurable idle cycle for different access condition: Write command finish (W2X), Read-to-Read (R2R)
- Supports zero address hold time with read/write operation and write buffer for write operation to enhance read/write performance (M05xxDN/DE Only)

6.5.3 Block Diagram

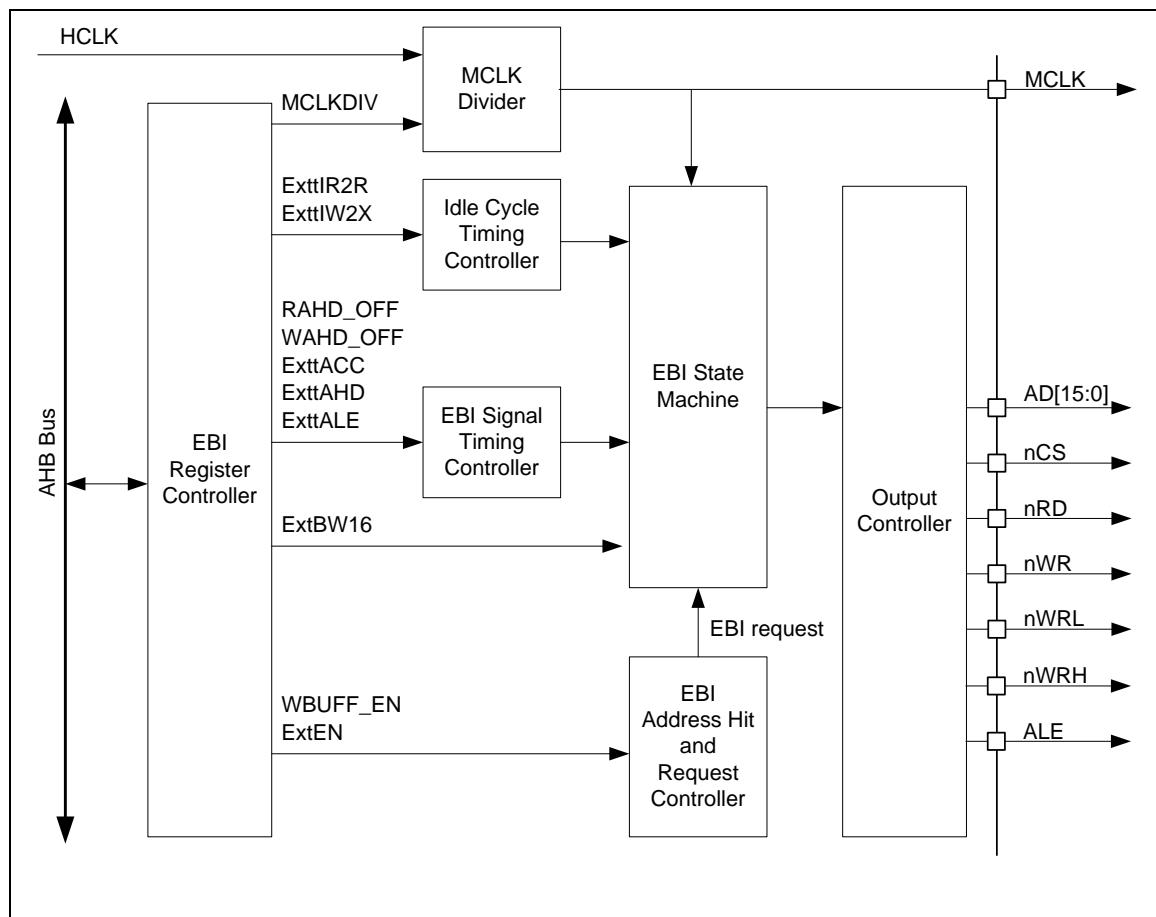

Figure 6-19 EBI Block Diagram

6.5.4 Basic Configuration

The basic configurations of EBI are as follows:

- EBI peripheral clock is enabled in AHBCLK[3].
- The AD[15:0] pins functions are configured in P0_MFP and P2_MFP registers; nRD, nWR and MCLK pins functions are configured in P3_MFP register; ALE and nCS pins functions are configured in P4_MFP register; nWRL and nWRH pins functions are configured in P1_MFP register.
-

6.5.5 Functional Description

6.5.5.1 EBI Area and Address Hit

The EBI mapping address is located at 0x6000_0000 ~ 0x6001_FFFF and the maximum available memory space is 128 Kbytes. When the system request address hits EBI's memory space, the corresponding EBI chip select signal (nCS) is assert and EBI state machine operates.

For an 8-bit device (64 Kbytes), EBI mapped this 64 Kbytes device to 0x6000_0000 ~ 0x6000_FFFF and 0x6001_0000 ~ 0x6001_FFFF simultaneously.

For a 16-bit device (128 Kbytes), EBI mapped this 128 Kbytes device to 0x6000_0000 ~ 0x6001_FFFF.

6.5.5.2 EBI Data Width Connection

The EBI controller supports to connect the external device whose address bus and data bus are multiplexed. For the external device with separated address and data bus, the connection to device needs additional logic (latch device) to latch the address. In this case, pin ALE is connected to the latch device to latch the address value. Pins AD0 ~ AD15 for 16-bit data width / Pins AD0 ~ AD7 for 8-bit data width are the input pins of the latch device, and the output pins of the latch device are connected to the Addr[15:0] of external device.

For 16-bit device, the AD[15:0] shared by address (Addr[15:0]) and 16-bit data (Data[15:0]). For 8-bit device, only AD[7:0] shared by address (Addr[7:0]) and 8-bit data (Data[7:0]), AD[15:8] is dedicated for address (Addr[15:8]) and could be connected to 8-bit device directly.

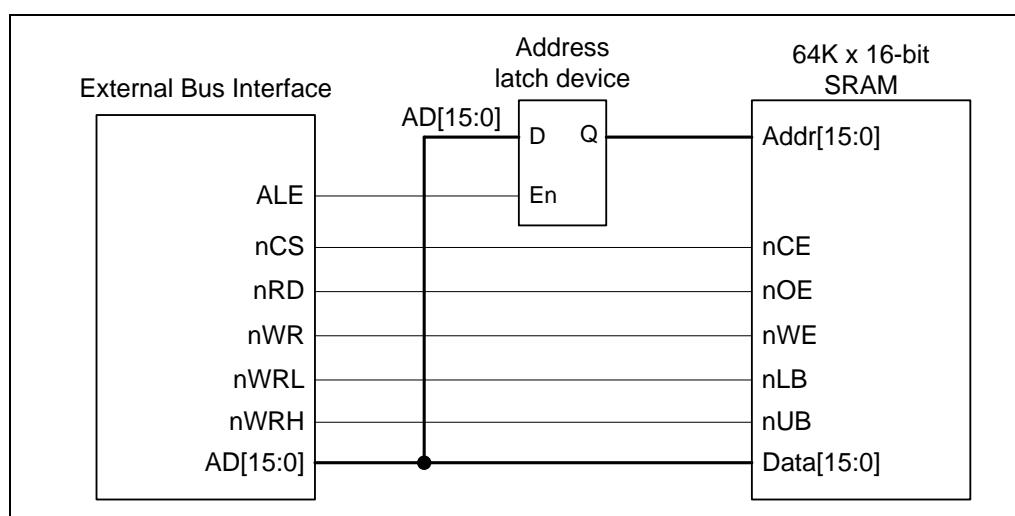

Figure 6-20 Connection of 16-bit EBI Data Width with 16-bit Device

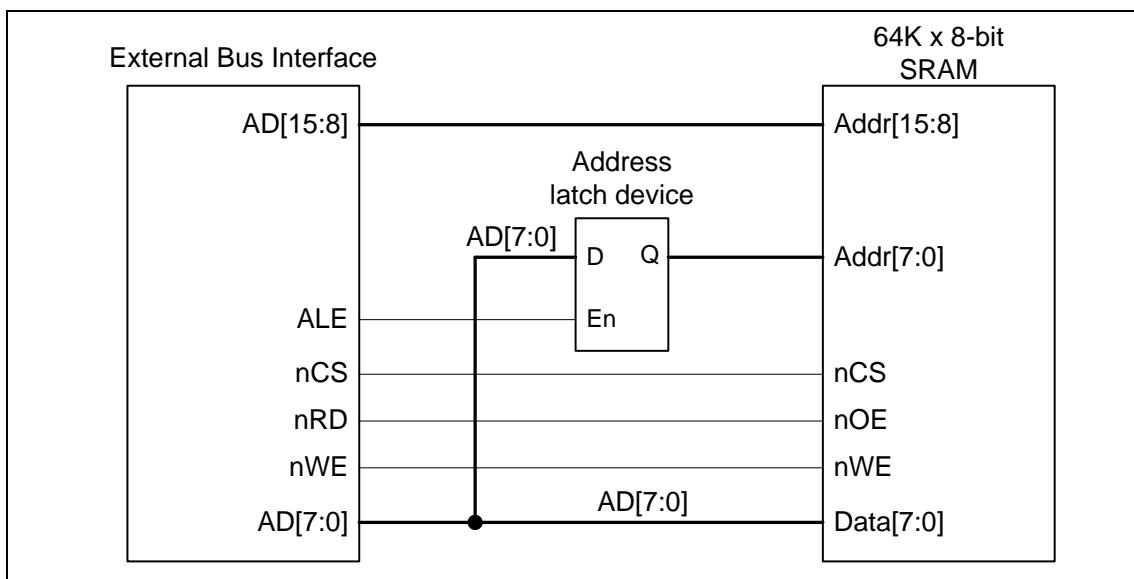

Figure 6-21 Connection of 8-bit EBI Data Width with 8-bit Device

When the system access data width is larger than EBI data width (8-bit / 16 bit data width), the EBI controller will finish a system access command by operating EBI access more than once. For example, if system requests a 32-bit data through EBI device, the EBI controller will operate accessing four times when setting EBI data width with 8-bit data width.

6.5.5.3 EBI Operating Control

MCLK Control

In the chip, all EBI signals will be synchronized by MCLK when EBI is operating. When the chip connects to the external device with slower operating frequency, the MCLK can divide most to 32 from HCLK by setting MCLKDIV[2:0]. Therefore, the EBI controller is suitable for a wide frequency range of EBI device. If MCLK frequency is set to the same as HCLK, EBI signals are synchronized by positive edge of MCLK, else by negative edge of MCLK.

Operation and Access Timing Control

At the start of EBI access, chip select signal (nCS) asserts to low and waits one MCLK for address setup time (tASU) for address stable. Then address latch enable signal (ALE) asserts to high after address is stable and keeps for a period of time (tALE) for address latch. After latch address, ALE signal asserts to low and waits one MCLK for address latch hold time (tLHD) and another one MCLK cycle (tA2D) that is inserted behind tLHD to be the bus turn-around time for address change to data. Then nRD signal asserts to low when read access or nWR signal asserts to low when write access. Then nRD or nWR signal asserts to high after keeps access time (tACC) for reading output stable or writing finish. After that, EBI signals keep for data access hold time (tAHD) and nCS signal asserts to high then address is released by current access control.

The EBI controller provides a flexible timing control for different external devices, as shown in the following table. In EBI timing control, tASU, tLHD and tA2D are all fixed to 1 MCLK cycle, tAHD

can modulate to 1 ~ 8 MCLK cycles by setting ExttAHD[2:0] or zero tAHD for read/write by setting RAHD_OFF/WAHD_OFF bit (only for M05xxDN/DE), tACC can modulate to 1 ~ 32 MCLK cycles by setting ExttACC[4:0], and tALE can modulate to 1 ~ 8 MCLK cycles by setting ExttALE[2:0].

Parameter	Value	Unit	Description
tASU	1	MCLK	Address Latch Setup Time.
tALE	1 ~ 8	MCLK	ALE High Period. Controlled by ExttALE[2:0] of EBICON[18:16].
tLHD	1	MCLK	Address Latch Hold Time.
tA2D	1	MCLK	Address To Data Delay (Bus Turn-Around Time).
tACC	1 ~ 32	MCLK	Data Access Time. Controlled by ExttACC[4:0] of EXTIME[7:3].
tAHD	1 ~ 8	MCLK	Data Access Hold Time. Controlled by ExttAHD[2:0] of EXTIME[10:8] to select 1 ~ 8 tAHD.
tAHD	0	MCLK	Setting RAHD_OFF/WAHD_OFF to select zero tAHD (only for M05xxDN/DE).
IDLE	0 ~ 15	MCLK	Idle Cycle. Controlled by ExtIR2R[3:0] of EXTIME[27:24] and ExtIW2X[3:0] of EXTIME[15:12].

Table 6-10 EBI Timing Table

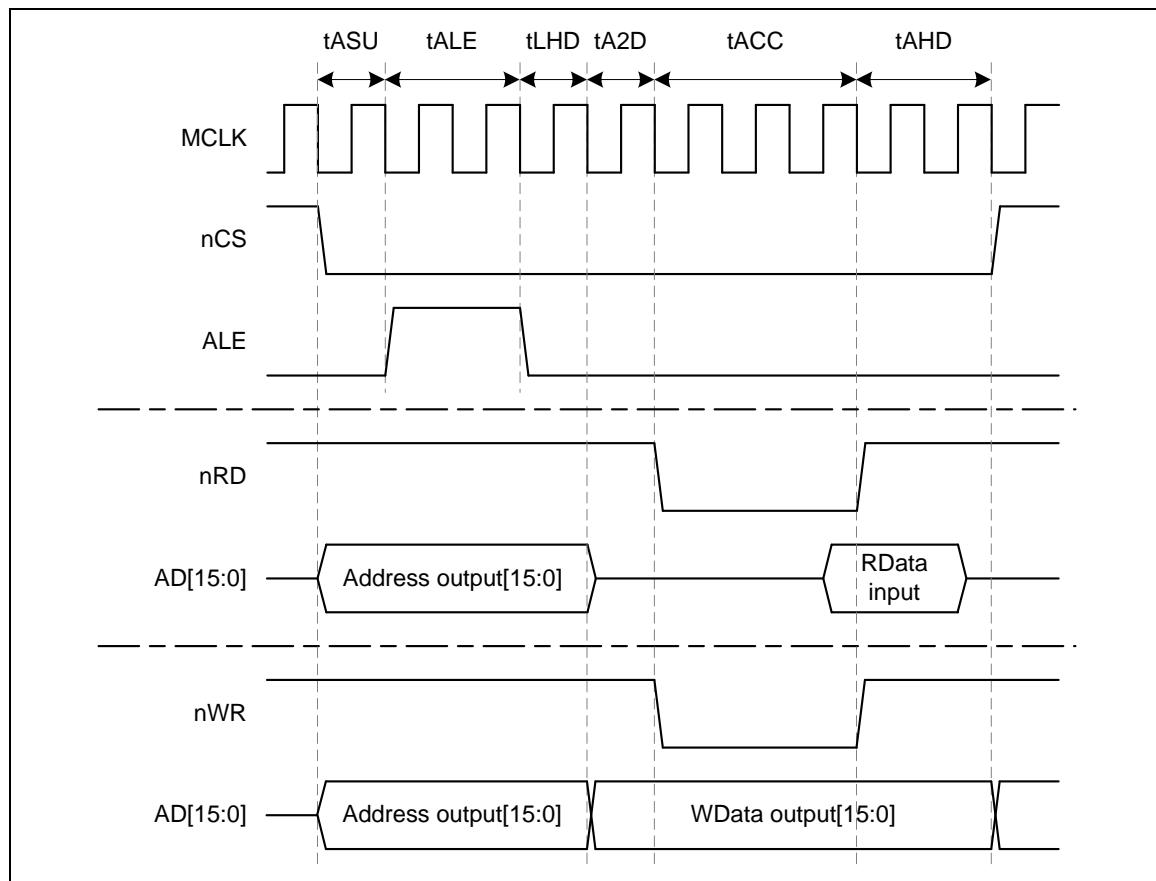

Figure 6-22 EBI Timing Control Waveform for 16-bit Data Width

The figure above shows an example of setting 16-bit data width for EBI application. In this example, AD0 ~ AD15 are used to be address[15:0] and data[15:0]. When ALE signal asserts to high, AD0 ~ AD15 are the address output. After address is latched (tLHD), ALE signal asserts to low and the AD[15:0] bus changes to high impedance to wait device output data in read access operation, or it is used to be write data output.

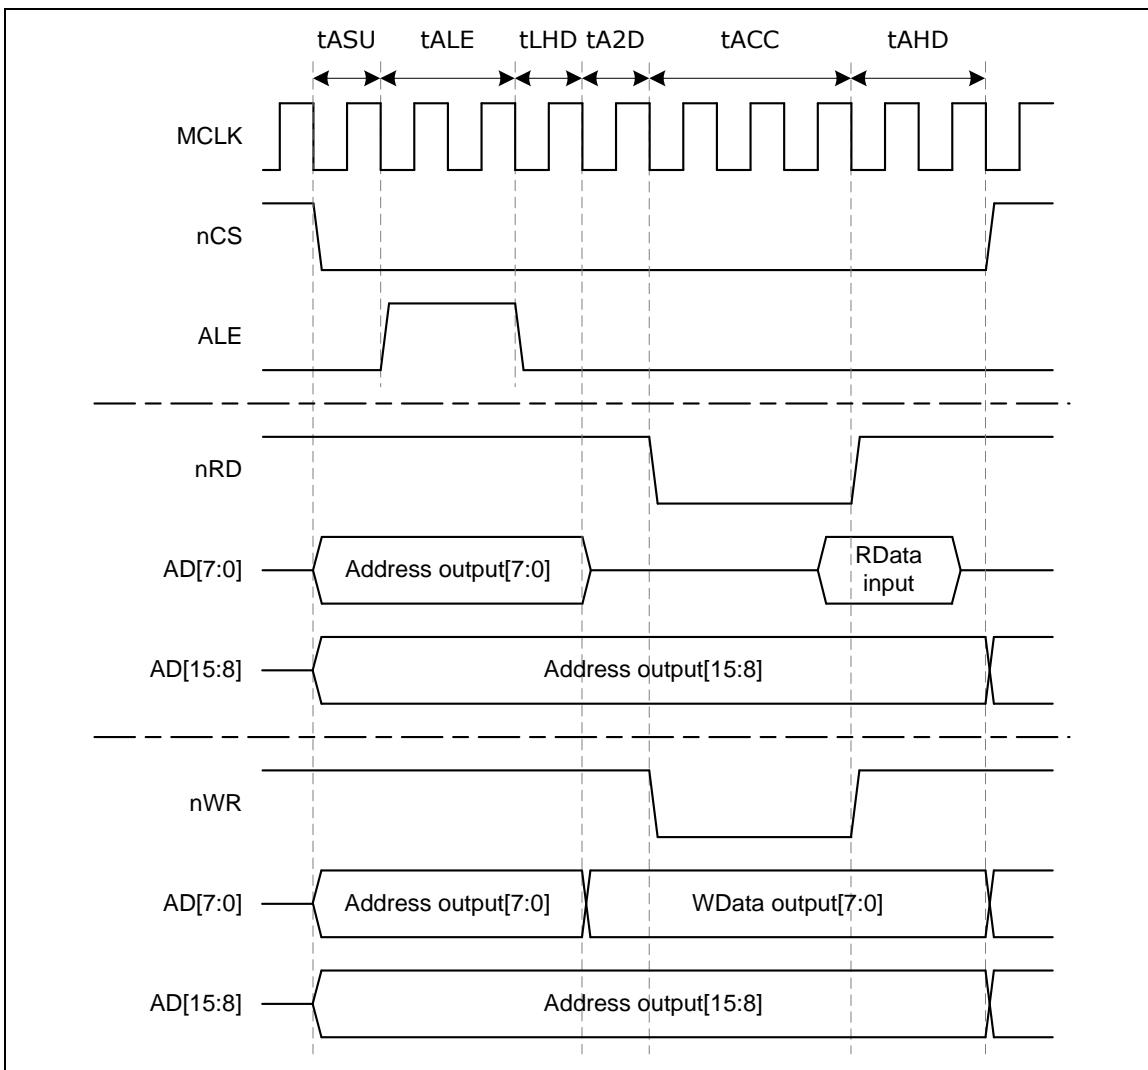

Figure 6-23 EBI Timing Control Waveform for 8-bit Data Width

The figure above shows an example of setting 8-bit data width for EBI application. The difference between 8-bit and 16-bit data width is AD8 ~ AD15. In 8-bit data width setting, and AD8 ~ AD15 are always the address[15:8] output so that the external latch needs only 8-bit width.

Insert Idle Cycle

When EBI is accessing continuously, bus conflict may occur if the device access time is much longer compared with system clock frequency. The EBI controller supplies additional idle cycle to solve this problem. During idle cycle period, all control signals of EBI bus are inactive. The

following figure shows idle cycle.

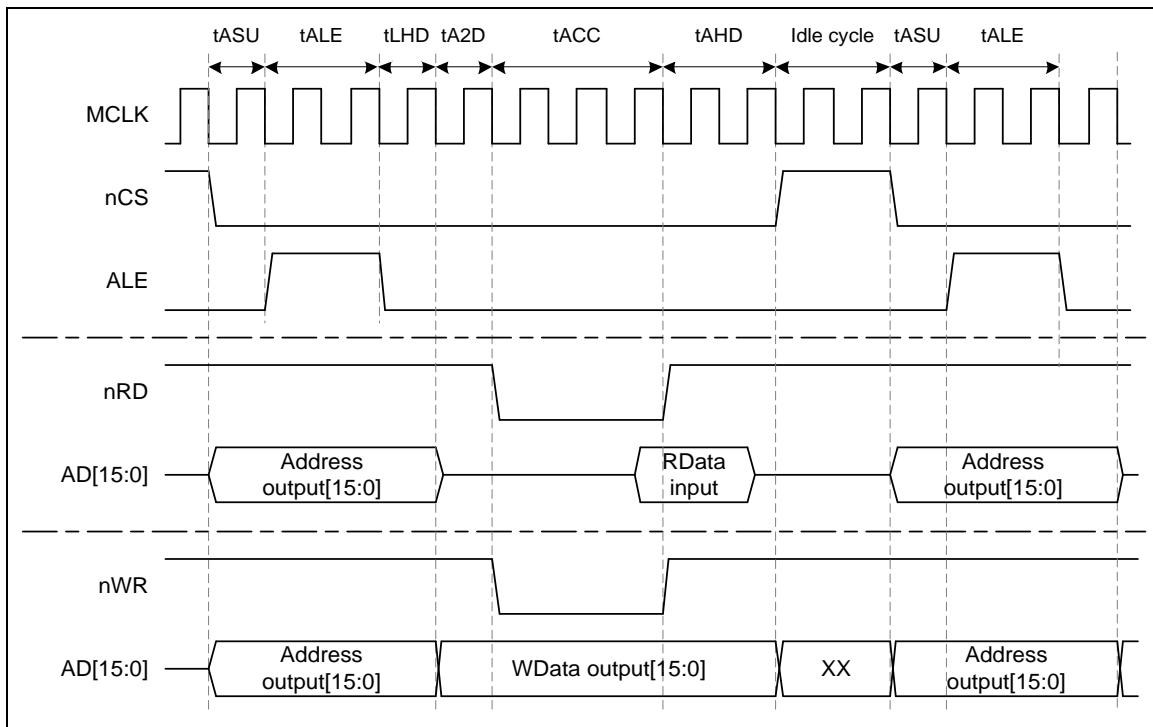

Figure 6-24 EBI Timing Control Waveform for Insert Idle Cycle

There are two conditions that EBI can insert idle cycle by timing control:

1. After write access
2. After read access and before next read access

By setting ExtIW2X[3:0] of EXTIME [15:12] and ExtIR2R[3:0] of the register EXTIME[27:24], the time of idle cycle can be specified from 0 ~ 15 MCLK.

Write Buffer (M05xxDN/DE Only)

When software write a data to external device through EBI bus, the EBI controller will start processing the write action immediately and the CPU is held until current EBI write action finish. User can enable write buffer function to improve CPU and EBI access performance. When EBI write buffer function is enabled, the CPU can continuous execute other instruction during EBI controller process the write action to external device. There is one exception condition for this case, if CPU executes another data access through EBI bus when EBI process write action, the CPU will be held.

6.5.6 Register Map

R: read only, W: write only, R/W: both read and write

Register	Offset	R/W	Description	Reset Value

6.6 General Purpose I/O (GPIO)

6.6.1 Overview

The NuMicro® M05xxBN and M05xxDN/DE has up to 40 General Purpose I/O pins to be shared with other function pins depending on the chip configuration. These 40 pins are arranged in 5 ports named as P0, P1, P2, P3 and P4. Each port has the maximum of 8 pins. Each of the 40 pins is independent and has the corresponding register bits to control the pin mode function and data.

The I/O type of each pin can be configured by software individually as Input, Push-pull output, Open-drain output or Quasi-bidirectional mode. After the chip is reset, the I/O mode of all pins is stay in quasi-bidirectional mode and each port data register Px_DOUT[7:0] resets to 0x000_00FF. Each I/O pin has a very weakly individual pull-up resistor which is about $110\text{ k}\Omega \sim 300\text{ k}\Omega$ for V_{DD} is from 5.0 V to 2.5 V.

6.6.2 Features

- Four I/O modes:
 - Input only with high impedance
 - Push-pull output
 - Open-drain output
- Quasi-bidirectional TTL/Schmitt trigger input mode selected by Px_MFP[23:16]
- I/O pin configured as interrupt source with edge/level setting
- I/O pin internal pull-up resistor enabled only in Quasi-bidirectional I/O mode
- Enabling the pin interrupt function will also enable the pin wake-up function
- Configurable default I/O mode of all pins after reset by CIOINI(CONFIG[10]) setting (M05xxDN/DE Only)
 - CIOINI = 0, all GPIO pins in Input tri-state mode after chip reset
 - CIOINI = 1, all GPIO pins in Quasi-bidirectional mode after chip reset

6.6.3 Basic Configuration

The GPIO pin functions are configured in P0_MFP, P1_MFP, P2_MFP, P3_MFP and P4_MFP registers.

6.6.4 Functional Description

6.6.4.1 Input Mode

Set Px_PMD (PMDn[1:0]) to 00 as the Px.n pin is in Input mode and the I/O pin is in tri-state (high impedance) without output drive capability. The Px_PIN value reflects the status of the corresponding port pins.

6.6.4.2 Push-pull Output Mode

Set Px_PMD (PMDn[1:0]) to 01 as the Px.n pin is in Push-pull output mode and the I/O pin supports digital output function with source/sink current capability. The bit value in the corresponding Px_DOUT[n] bit is driven on the pin.

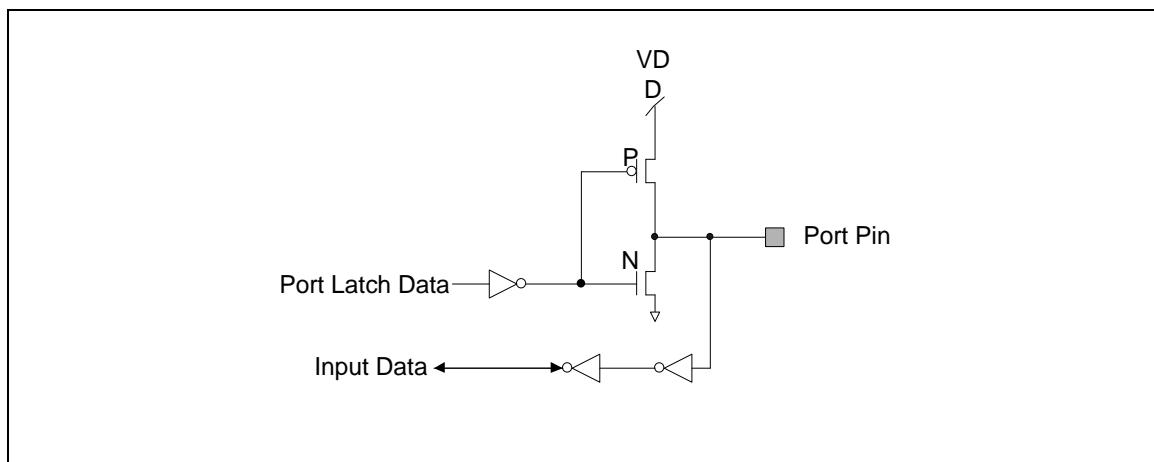

Figure 6-25 Push-Pull Output

6.6.4.3 Open-drain Output Mode

Set Px_PMD (PMDn[1:0]) to 10 as the Px.n pin is in Open-drain mode and the digital output function of I/O pin only supports sink current capability, an external pull-up resistor is needed for driving high state. If the bit value in the corresponding Px_DOUT[n] bit is 0, the pin drive a low output on the pin. If the bit value in the corresponding Px_DOUT[n] bit is 1, the pin output drives high that is controlled by external pull-up resistor.

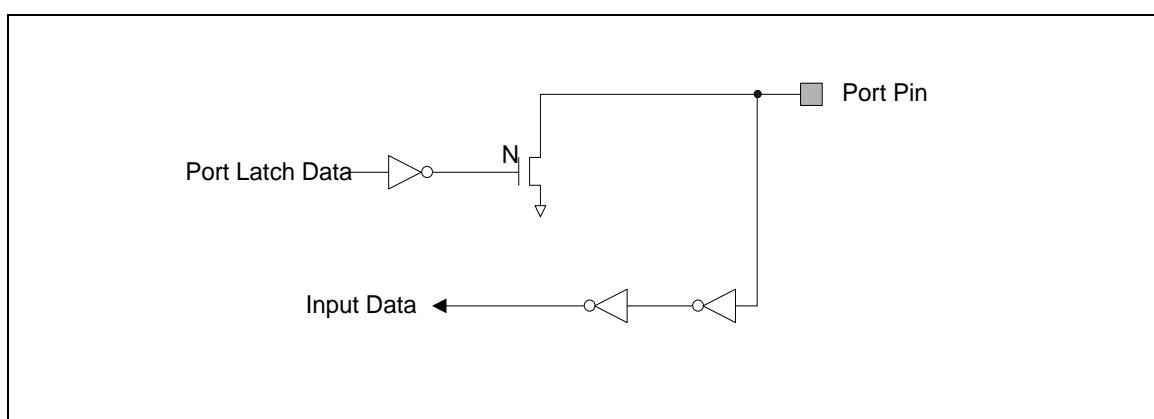

Figure 6-26 Open-Drain Output

6.6.4.4 Quasi-bidirectional Mode

Set Px_PMD (PMDn[1:0]) to 11 as the Px.n pin is in Quasi-bidirectional mode and the I/O pin supports digital output and input function at the same time but the source current is only up to hundreds of μ A. Before the digital input function is performed the corresponding Px_DOUT[n] bit must be set to 1. The Quasi-bidirectional output is common on the 80C51 and most of its derivatives. If the bit value in the corresponding Px_DOUT[n] bit is 0, the pin drive a low output on the pin. If the bit value in the corresponding Px_DOUT[n] bit is 1, the pin will check the pin value. If pin value is high, no action takes. If pin state is low, then pin will drive strong high with 2 clock cycles on the pin and then disable the strong output drive. Meanwhile, the pin status is controlled by internal pull-up resistor.

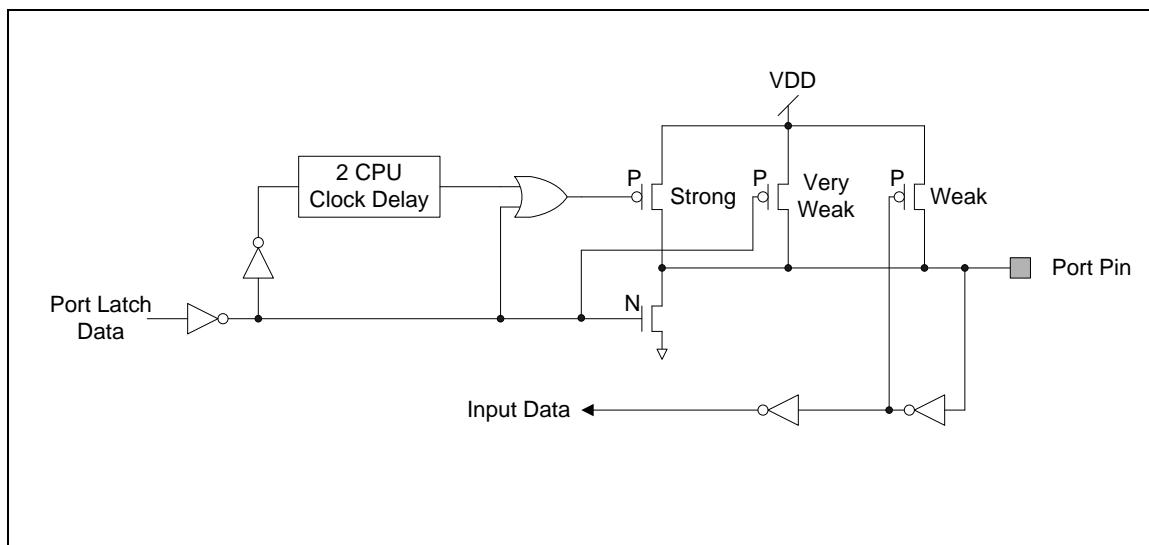

Figure 6-27 Quasi-Bidirectional I/O Mode

6.6.5 GPIO Interrupt and Wake-up Function

Each GPIO pin can be set as chip interrupt source by setting correlative Px_IEN bit and Px_IMD. There are five types of interrupt condition can be selected: low level trigger, high level trigger, falling edge trigger, rising edge trigger and both rising and falling edge trigger. For edge trigger condition, user can enable input signal de-bounce function to prevent unexpected interrupt happened which caused by noise. The de-bounce clock source and sampling cycle period can be set through DBNCECON register.

The GPIO can also be the chip wake-up source when chip enters Idle/Power-down mode. The setting of wake-up trigger condition is the same as GPIO interrupt trigger, but there are two things need to be noticed (only for M05xxBN) if using GPIO as chip wake-up source.

1. To ensure the I/O status before entering Idle/Power-down mode

When using toggle GPIO to wake-up system, user must make sure the I/O status before entering Idle/Power-down mode according to the relative wake-up settings.

For example, if configuring the wake-up event occurred by I/O rising edge/high level trigger, user must make sure the I/O status of specified pin is at low level before entering Idle/Power-down mode; and if configure I/O falling edge/low level trigger to trigger a wake-up event, user must make sure the I/O status of specified pin is at high level before entering Power-down mode.

2. To disable the I/O de-bounce function before entering Idle/Power-down mode

If the specified wake-up I/O pin with enabling input signal de-bounce function, system will encounter two GPIO interrupt events while the system is woken up by this GPIO pin. One interrupt event is caused by wake-up function, the other is caused by I/O input de-bounce function. User should be disable the de-bounce function before entering Idle/Power-down mode to avoid the second interrupt event occurred after system waken up.

6.7 Timer Controller (TMR)

6.7.1 Overview

The Timer Controller includes four 32-bit timers, TIMER0 ~ TIMER3, allowing user to easily implement a timer control for applications. The timer can perform functions, such as frequency measurement, delay timing, clock generation, and event counting by external input pins, and interval measurement by external capture pins.

6.7.2 Features

- Four sets of 32-bit timers with 24-bit up counter and one 8-bit prescale counter
- Independent clock source for each timer
- Provides four timer counting modes: one-shot, periodic, toggle and continuous counting
- Time-out period = (Period time of timer clock input) * (8-bit prescale counter + 1) * (24-bit TCMP)
- Maximum counting cycle time = $(1 / T \text{ MHz}) * (2^8) * (2^{24})$, T is the period time of timer clock
- 24-bit up counter value is readable through TDR (Timer Data Register)
- Supports event counting function to count the input event from external counter pin (T0~T3)
- 24-bit capture value is readable through TCAP (Timer Capture Data Register)
- Supports external capture pin (T0EX~T3EX) for interval measurement
- Supports external capture pin (T0EX~T3EX) to reset 24-bit up counter
- The following new features are only available on M05xxDN/DE:
 - ◆ Supports chip wake-up from Idle/Power-down mode if a timer interrupt signal is generated
 - ◆ Supports internal capture triggered while internal ACMP output signal transition
 - ◆ Supports Inter-Timer trigger mode

6.7.3 Block Diagram

The Timer Controller block diagram and clock control are shown as follows.

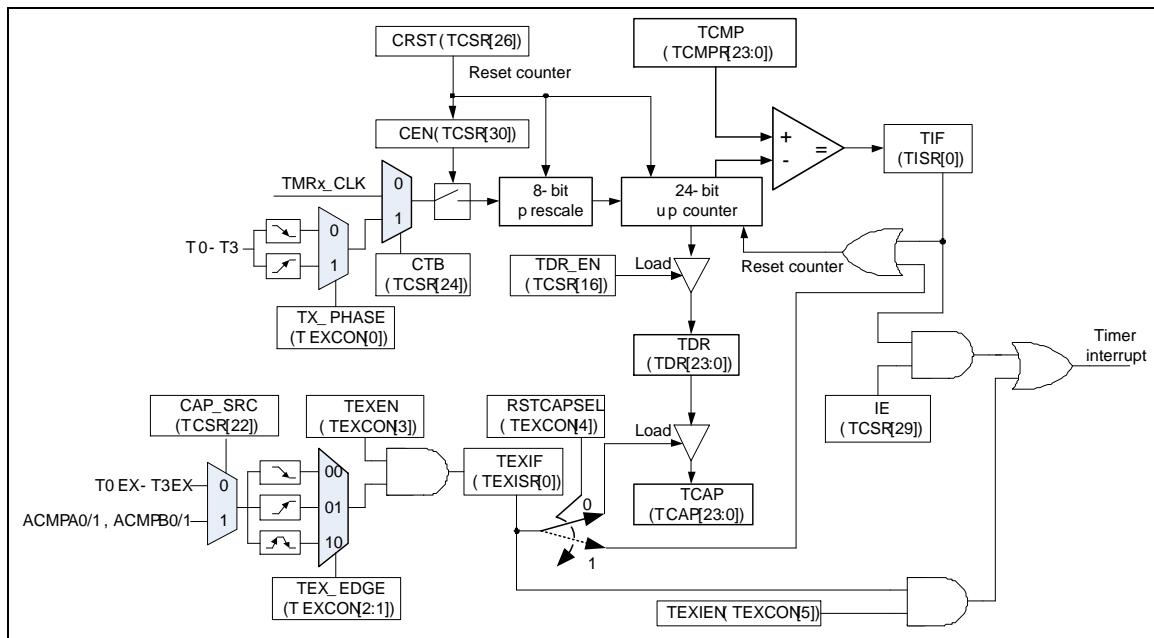

Figure 6-28 Timer Controller Block Diagram

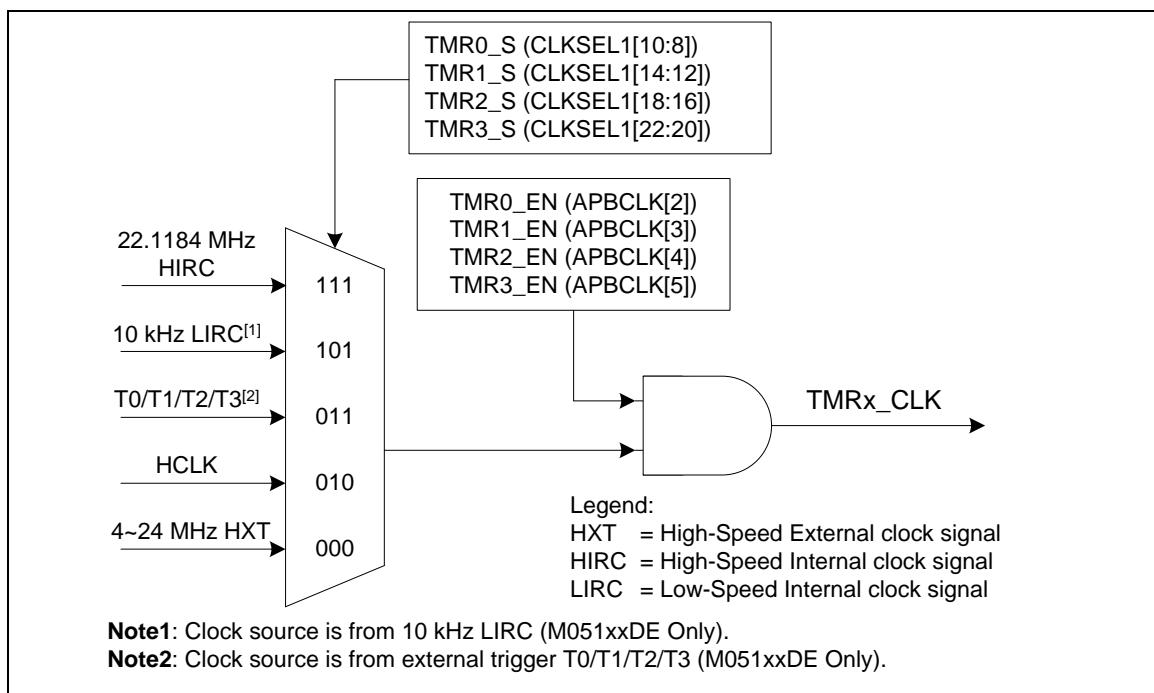

Figure 6-29 Clock Source of Timer Controller

6.7.4 Basic Configuration

The peripheral clock source of Timer0 ~ Timer3 can be enabled in APBCLK[5:2] and selected as

different frequency in CLKSEL1[10:8] for Timer0, CLKSEL1[14:12] for Timer1, CLKSEL1[18:16] for Timer2 and CLKSEL1[22:20] for Timer3.

6.7.5 Functional Description

6.7.5.1 Timer Interrupt Flag

Timer controller supports two interrupt flags; one is TIF flag and its set while timer counter value (TDR) matches the timer compared value (TCMP), the other is TEXIF flag and its set when the transition on the TxEX pin associated TEX_EDGE setting.

6.7.5.2 Timer Counting Operation Mode

Timer controller provides four timer counting modes: one-shot, periodic, toggle-output and continuous counting operation modes:

One-shot Mode

If timer controller is configured at one-shot mode (TCSR[28:27] is 00) and CEN (TCSR[30]) bit is set, the timer counter starts up counting. Once the TDR value reaches TCMP value, the TIF flag will be set to 1, TDR value and CEN bit is cleared by timer controller then timer counting operation stops. In the meantime, if the IE (TCSR[29]) bit is enabled, the timer interrupt signal is generated and sent to NVIC to inform CPU also.

Periodic Mode

If timer controller is configured at periodic mode (TCSR[28:27] is 01) and CEN bit is set, the timer counter starts up counting. Once the TDR value reaches TCMP value, the TIF flag will be set to 1, TDR value will be cleared by timer controller and timer counter operates counting again. In the meantime, if the IE bit is enabled, the timer interrupt signal is generated and sent to NVIC to inform CPU also. In this mode, timer controller operates counting and compares with TCMP value periodically until the CEN bit is cleared by software.

Toggle-output Mode

If timer controller is configured at toggle-out mode (TCSR[28:27] is 10) and CEN bit is set, the timer counter starts up counting. The counting operation of toggle-out mode is almost the same as periodic mode, except toggle-out mode has associated T0~T3 pin to output signal while specify TIF bit is set. Thus, the toggle-output signal on T0~T3 pin is changing back and forth with 50% duty cycle.

Continuous Counting Mode

If timer controller is configured at continuous counting mode (TCSR[28:27] is 11) and CEN bit is set, the timer counter starts up counting. Once the TDR value reaches TCMP value, the TIF flag will be set to 1 and TDR value keeps up counting. In the meantime, if the IE bit is enabled, the timer interrupt signal is generated and sent to NVIC to inform CPU also. User can change different TCMP value immediately without disabling timer counting and restarting timer counting in this mode.

For example, TCMP value is set as 80, first. The TIF flag will set to 1 when TDR value is equal to 80, timer counter is kept counting and TDR value will not goes back to 0, it continues to count 81, 82, 83, ... to 2^{24} -1, 0, 1, 2, 3, ... to 2^{24} -1 again and again. Next, if software programs TCMP value as 200 and clears TIF flag, the TIF flag will set to 1 again when TDR value reaches to 200. At last, software programs TCMP as 500 and clears TIF flag, the TIF flag will set to 1 again when TDR value reaches to 500.

In this mode, the timer counting is continuous. So, this operation mode is called as continuous counting mode.

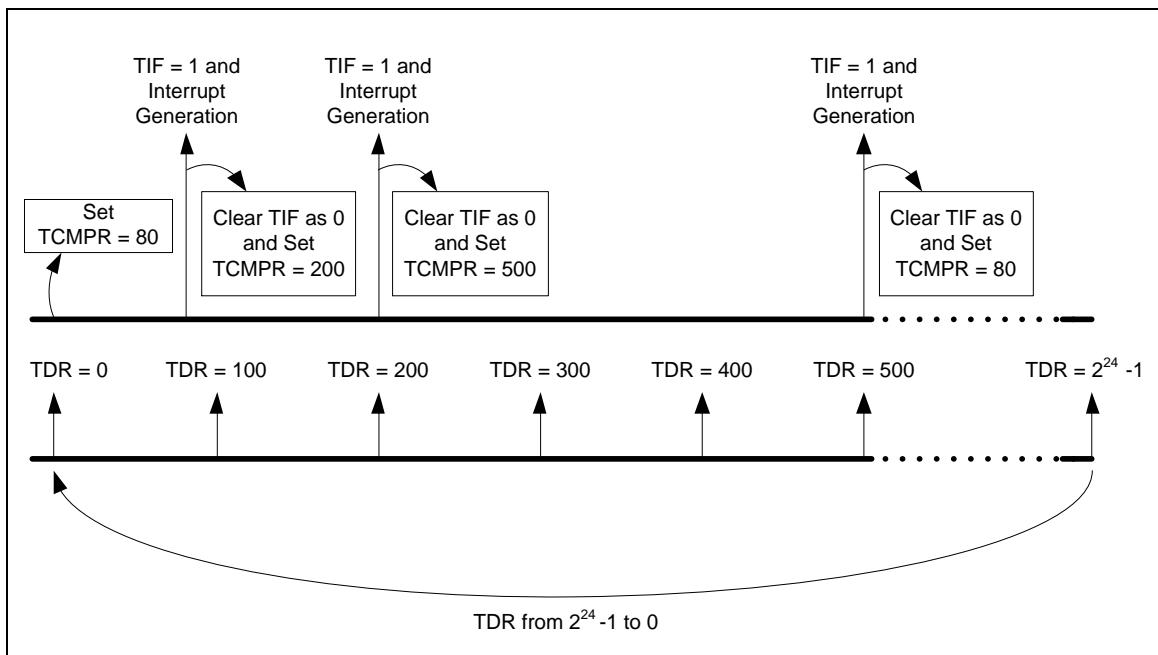

Figure 6-30 Continuous Counting Mode

6.7.5.3 Event Counting Mode

Timer controller also provides an application which can count the input event from Tx pin ($x=0\sim 3$) and the number of event will reflect to TDR value. It is also called as event counting function. In this function, CTB (TCSR[24]) bit should be set and the timer peripheral clock source should be set as HCLK.

Software can enable or disable Tx pin de-bounce circuit by TCDB (TEXCON[7]) bit. The input event frequency should be less than 1/3 HCLK if Tx pin de-bounce disabled or less than 1/8 HCLK if Tx pin de-bounce enabled to assure the returned TDR value is incorrect, and software can also select edge detection phase of Tx pin by TX_PHASE (TEXCON[0]) bit.

In event counting mode, the timer counting operation mode can be selected as one-shot, periodic and continuous counting mode to counts the TDR value by input event from Tx pin.

6.7.5.4 Event Capture Mode

The event capture function is used to capture TDR value to TCAP value while edge transition detected on TxEX pin ($x=0\sim 3$). In this mode, RSTCAPSEL (TEXCON[4]) bit should be as 0 for select TxEX transition is using as the event capture function and the timer peripheral clock source should be set as HCLK.

Software can enable or disable TxEX pin de-bounce circuit by TEXDB (TEXCON[6]) bit. The transition frequency of TxEX pin should be less than 1/3 HCLK if TxEX pin de-bounce disabled or less than 1/8 HCLK if TxEX pin de-bounce enabled to assure the capture function can be work normally, and software can also select edge transition detection of TxEX pin by TEX_EDGE (TEXCON[2:1]) bits.

In event capture mode, software does not consider what timer counting operation mode is selected, the capture event occurred only if edge transition on TxEX pin is detected.

6.7.5.5 Event Reset Counter Mode

It also provides reset counter function to reset TDR value while edge transition detected on TxEX pin ($x= 0\sim 3$). In this mode, most the settings are the same as event capture function except RSTCAPSEL (TEXCON[4]) bit should be as 1 for select TxEX transition is using as the event reset counter.

6.7.5.6 Inter-Timer Trigger Capture Mode (M05xxDN/DE Only)

In this mode, the Timer0/2 will be forced in counter mode, counting with external event, and will generate an internal signal (INTR_TMR_TRG) to trigger Timer1/3 start or stop counting. Also, the Timer1/3 will be forced in capture mode and start/stop trigger-counting by Timer0/2 counter status.

Setting Timer0 Inter-timer Trigger Capture enabled, trigger-counting capture function is forced on Timer1. Setting Timer2 Inter-Timer Trigger enabled, trigger-counting capture function is forced on Timer3.

Start Trigger

While INTR_TRG_EN bit in Timer0/2 is set, the Timer0/2 will make a rising-edge transition of INTR_TMR_TRG while Timer0/2 24-bit counter value (TDR) is counting from 0x0 to 0x1 and Timer1/3 counter will start counting immediately and automatically.

Stop Trigger

When Timer0/2 TDR reaches the Timer0/2 TCMPR value, the Timer0/2 will make a falling-edge transition of INTR_TMR_TRG. Then Timer0/2 counter mode function will be disabled and INTR_TRG_EN bit will be cleared by hardware then Timer1/3 will stop counting also. At the same time, the Timer1/3 TDR value will be saved into Timer1/3 TCAP register.

User can use inter-timer trigger mode to measure the period of external event (Tx) more precisely. Figure 6-31 shows the sample flow of Inter-Timer Trigger Capture Mode for Timer0 as event counter mode and Timer1 as trigger-counting capture mode.

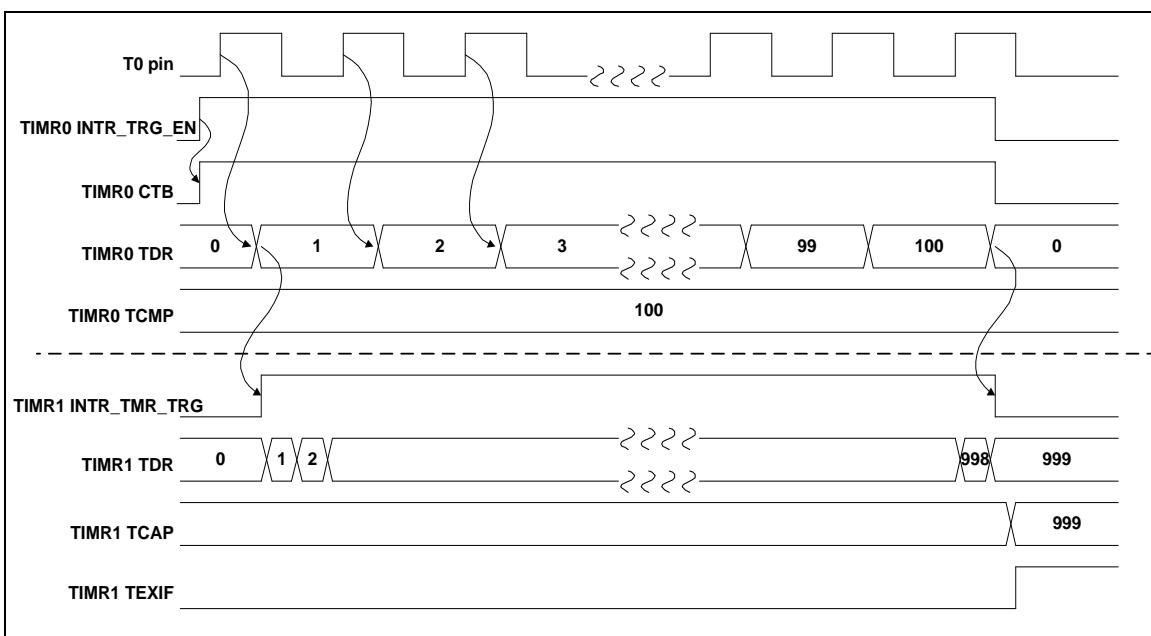

Figure 6-31 Inter-Timer Trigger Capture Timing

6.7.5.7 Internal Capture Trigger from ACMP (Only for M05xxDN/DE)

The event capture function also can be triggered by internal output signal transition on ACMPA0(Timer0), ACMPA1(Timer1), ACMPB0(Timer2) or ACMPB1(Timer3) output. The detail setting of capture function is the same as previous descriptions in Event Capture Mode.

Bits	Description	
[31]	DBGACK_TMR	ICE Debug Mode Acknowledge Disable (Write Protect) 0 = ICE debug mode acknowledgement effects TIMER counting. Timer counter will be held while CPU is held by ICE. 1 = ICE debug mode acknowledgement Disabled. Timer counter will keep going no matter CPU is held by ICE or not.
[30]	CEN	Timer Enable Control 0 = Stops/Suspends counting. 1 = Starts counting. Note1: In stop status, and then set CEN to 1 will enable the 24-bit up counter to keep counting from the last stop counting value. Note2: This bit is auto-cleared by hardware in one-shot mode (TCSR[28:27] = 00) when the timer interrupt flag (TIF) is generated.
[29]	IE	Interrupt Enable Control 0 = Timer Interrupt function Disabled. 1 = Timer Interrupt function Enabled. If this bit is enabled, when the timer interrupt flag (TIF) is set to 1, the timer interrupt signal is generated and inform to CPU.
[28:27]	MODE	Timer Operating Mode 00 = The Timer controller is operated in One-shot mode. 01 = The Timer controller is operated in Periodic mode.

		10 = The Timer controller is operated in Toggle-output mode. 11 = The Timer controller is operated in Continuous Counting mode.
[26]	CRST	Timer Reset 0 = No effect. 1 = Reset 8-bit prescale counter, 24-bit up counter value and CEN bit if CACT is 1.
[25]	CACT	Timer Active Status (Read Only) This bit indicates the 24-bit up counter status. 0 = 24-bit up counter is not active. 1 = 24-bit up counter is active.
[24]	CTB	Counter Mode Enable Control This bit is for external counting pin function enabled. When timer is used as an event counter, this bit should be set to 1 and select HCLK as timer clock source. Please refer to section 6.7.5.3 for detail description. 0 = External event counter mode Disabled. 1 = External event counter mode Enabled.
[23]	WAKE_EN	Wake-up Function Enable Control (M05xxDN/DE Only) 0 = Wake-up trigger event Disabled. 1 = Wake-up trigger event Enabled.
[22]	CAP_SRC	Capture Pin Source Selection (M05xxDN/DE Only) 0 = Capture Function source is from TxEx pin. 1 = Capture Function source is from internal ACMPx output signal.
[21]	TOUT_SEL	Toggle-output Pin Selection (M05xxDN/DE Only) 0 = Toggle-output pin is from Tx pin. 1 = Toggle-output pin is from TxEx pin.
[20]	PERIODIC_SEL	Periodic Mode Behavior Selection Enable (M05xxDN/DE Only) 0 = The behavior selection in periodic mode is Disabled. When user updates TCMP while timer is running in periodic mode, TDR will be reset to default value. 1 = The behavior selection in periodic mode is Enabled. When user update TCMP while timer is running in periodic mode, the limitations as bellows list, If updated TCMP value > TDR, TCMP will be updated and TDR keep running continually. If updated TCMP value = TDR, timer time-out interrupt will be asserted immediately. If updated TCMP value < TDR, TDR will be reset to default value.
[19]	INTR_TRG_EN	Inter-timer Trigger Mode Enable Control (M05xxDN/DE Only) Setting this bit will enable the inter-timer trigger capture function. The Timer0/2 will be in counter mode and counting with external clock source or event. Also, Timer1/3 will be in trigger-counting mode of capture function. 0 = Inter-Timer Trigger Capture mode Disabled. 1 = Inter-Timer Trigger Capture mode Enabled. Note: For Timer1/3, this bit is ignored and the read back value is always 0.
[18:17]	Reserved	Reserved.
[16]	TDR_EN	Data Load Enable Control When TDR_EN is set, TDR (Timer Data Register) will be updated continuously with the 24-bit up-timer value as the timer is counting. 0 = Timer Data Register update Disabled. 1 = Timer Data Register update Enabled while Timer counter is active.

[15:8]	Reserved	Reserved.
[7:0]	PRESCALE	Prescale Counter Timer input clock source is divided by (PRESCALE+1) before it is fed to the Timer up counter. If this field is 0 (PRESCALE = 0), then there is no scaling.

6.8 PWM Generator and Capture Timer (PWM)

6.8.1 Overview

The NuMicro® M051 series has two sets of PWM groups supporting a total of four sets of PWM generators, which can be configured as eight independent PWM outputs, PWM0~PWM7, or as four complementary PWM pairs, (PWM0, PWM1), (PWM2, PWM3), (PWM4, PWM5) and (PWM6, PWM7) with 4 programmable Dead-zone generators.

Each PWM generator has one 8-bit prescaler, one clock divider with 5 divided frequencies (1, 1/2, 1/4, 1/8, 1/16), two PWM Timers including two clock selectors, two 16-bit PWM counters for PWM period control, two 16-bit comparators for PWM duty control and one Dead-zone generator. The 4 sets of PWM generators provide eight independent PWM period interrupt flags set by hardware when the corresponding PWM period down counter reaches 0. Each PWM period interrupt source with its corresponding enable bit can cause CPU to request PWM interrupt. The PWM generators can be configured as one-shot mode to produce only one PWM cycle signal or auto-reload mode to output PWM waveform continuously.

When DZEN01 (PCR[4]) is set, PWM0 and PWM1 perform complementary PWM paired function; the paired PWM period, duty and Dead-zone are determined by PWM0 timer and Dead-zone generator 0. Similarly, the complementary PWM pairs of (PWM2, PWM3), (PWM4, PWM5) and (PWM6, PWM7) are controlled by PWM2, PWM4 and PWM6 timers and Dead-zone generator 2, 4 and 6, respectively. Refer to figures below for the architecture of PWM Timers.

To prevent PWM driving output pin with unsteady waveform, the 16-bit period down counter and 16-bit comparator are implemented with double buffer. When user writes data to counter/comparator buffer registers, the updated value will be loaded into the 16-bit down counter/ comparator at the time down counter reaching 0. The double buffering feature avoids glitch at PWM outputs.

When the 16-bit period down counter reaches 0, the interrupt request is generated. If PWM-Timer is set as Auto-reload mode when the down counter reaches 0, it is reloaded with PWM Counter Register (CNRx) automatically and then starts decreasing repeatedly. If the PWM-Timer is set as one-shot mode, the down counter will stop and generate one interrupt request when it reaches 0.

The value of PWM counter comparator is used for pulse high width modulation. The counter control logic changes the output to high level when down-counter value matches the value of compare register.

The alternate feature of the PWM-Timer is digital input Capture function. If Capture function is enabled the PWM output pin is switched as capture input mode. The Capture0 and PWM0 share one timer which is included in PWM0 and the Capture1 and PWM1 share PWM1 timer, and etc. Therefore user must set the PWM-Timer before enabling the Capture feature. After capture feature is enabled, the capture always latched PWM-counter to Capture Rising Latch Register (CRLR) when input channel has a rising transition and latched PWM-counter to Capture Falling Latch Register (CFLR) when input channel has a falling transition. Capture channel 0 interrupt is programmable by setting CRL_IE0 (CCR0[1]) (Rising latch Interrupt enable) and CFL_IE0 (CCR0[2]) (Falling latch Interrupt enable) to decide the condition of interrupt occur. Capture channel 1 has the same feature by setting CRL_IE1 (CCR0[17]) and CFL_IE1 (CCR0[18]). The capture channel 2 to channel 3 on each group have the same feature by setting the corresponding control bits in CCR2. For each group, whenever Capture issues Interrupt 0/1/2/3, the PWM counter 0/1/2/3 will be reload at this moment.

The maximum captured frequency that PWM can capture is confined by the capture interrupt latency. When capture interrupt occurred, software will do at least three steps, including: Read PIIR to get interrupt source, read CRLRx/CFLRx ($x = 0\sim 3$) to get capture value and finally write 1 to clear PIIR to 0. If interrupt latency will take time T_0 to finish, the capture signal mustn't transition during this interval (T_0). In this case, the maximum capture frequency will be $1/T_0$.

6.8.2 Features

PWM function:

PWM group has two PWM generators. Each PWM generator supports one 8-bit prescaler, one clock divider, two PWM-Timers (down counter), one dead-zone generator and two PWM outputs.

- Up to 2 PWM groups (PWMA/PWMB) to support 8 PWM channels or 4 complementary PWM paired channels
- Each PWM group has two PWM generators with each PWM generator supporting one 8-bit prescaler, two clock dividers, two PWM-Timers, one Dead-zone generator and two PWM outputs.
- Up to 16-bit resolution
- One-shot or Auto-reload mode
- Edge-aligned type or Center-aligned type option
- PWM trigger ADC start-to-conversion

Capture function:

- Timing control logic shared with PWM generators
- Supports 8 Capture input channels shared with 8 PWM output channels
- Each channel supports one rising latch register (CRLRx), one falling latch register (CFLRx) and Capture interrupt flag (CAPIFx)

6.8.3 Block Diagram

The following figures illustrate the architecture of PWM in pair (e.g. PWM-Timer 0/1 are in one pair and PWM-Timer 2/3 are in another one, and so on.).

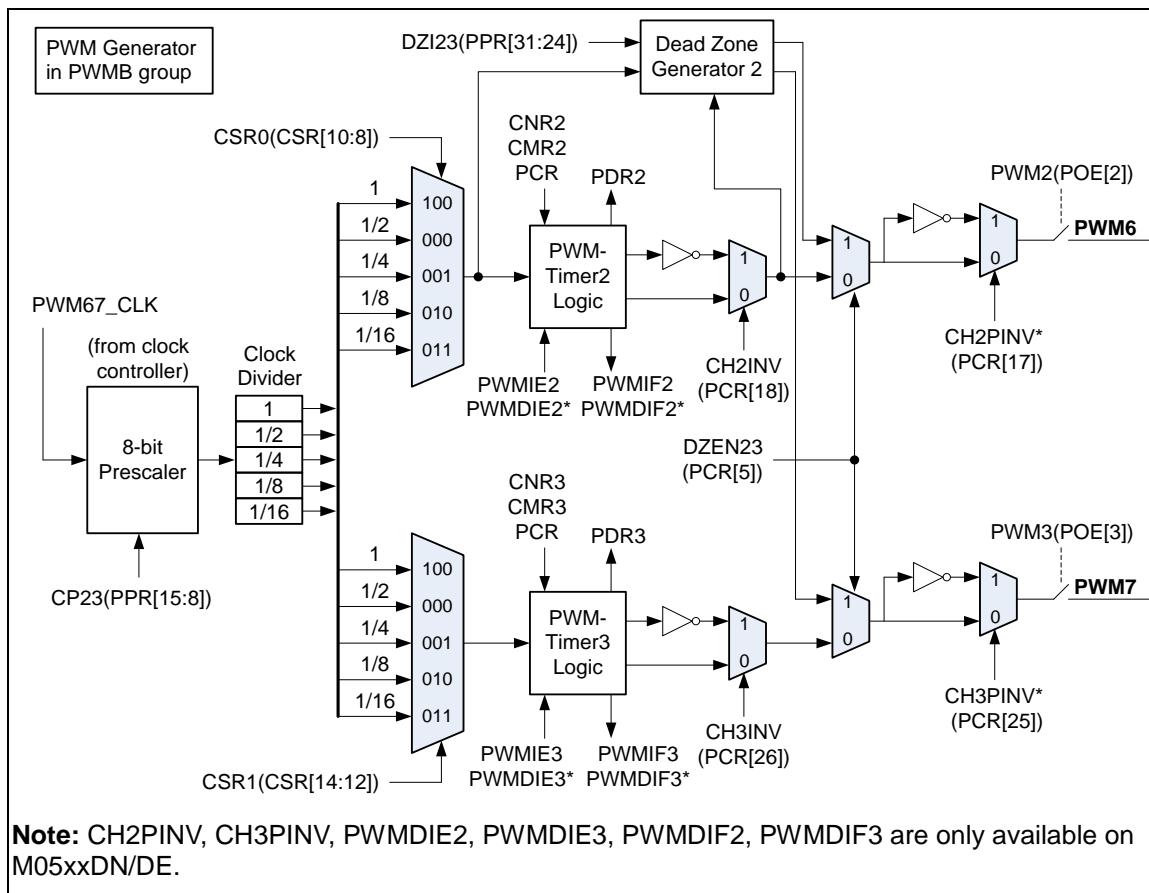

Figure 6-39 PWM Generator 6 Architecture Diagram

6.8.4 Basic Configuration

The PWM pin functions are configured in P2_MFP and P4_MFP registers.

The PWM clock can be enabled in APBCLK[23:20]. The PWM clock source is selected by CLKSEL1[31:28] and CLKSEL2[7:4].

6.8.5 Functional Description

6.8.5.1 PWM-Timer Operation

On M05xxBN, the PWM controller supports only one operation types: Edge-aligned. On M05xxDN/DE, the PWM controller supports 2 operation types: Edge-aligned and Center-aligned.

Edge-aligned PWM (Down-counter)

In Edge-aligned PWM Output mode, the 16 bits PWM counter will starts down-counting from CNRx to match with the value of the duty cycle CMRx (old), when this happened it will toggle the PWMx generator output to low. The counter will continue down-counting to zero, at this moment, it toggles the PWMx generator output to high and CMRx(new) and CNRx(new) are updated with CHxMODE=1 and request the PWM interrupt if PWM interrupt is enabled(PIERx=1).

The PWM period and duty control are configured by PWM down-counter register (CNR) and PWM comparator register (CMR). The PWM-Timer timing operation is shown below. The pulse width modulation follows the formula as shown below and the legend of PWM-Timer Comparator is shown in the note that the corresponding GPIO pins must be configured as PWM function (enable POE and disable CAPENR) for the corresponding PWM channel.

- PWM frequency = $\text{PWM}_{xy_CLK}/[(\text{prescale}+1)*(\text{clock divider})*(\text{CNR}+1)]$; where xy, could be 01, 23, 45 or 67, depends on selected PWM channel.
- Duty ratio = $(\text{CMR}+1)/(\text{CNR}+1)$
- $\text{CMR} \geq \text{CNR}$: PWM output is always high
- $\text{CMR} < \text{CNR}$: PWM low width = $(\text{CNR}-\text{CMR})$ unit^[1]; PWM high width = $(\text{CMR}+1)$ unit
- $\text{CMR} = 0$: PWM low width = (CNR) unit; PWM high width = 1 unit

Note [1]: unit = one PWM clock cycle.

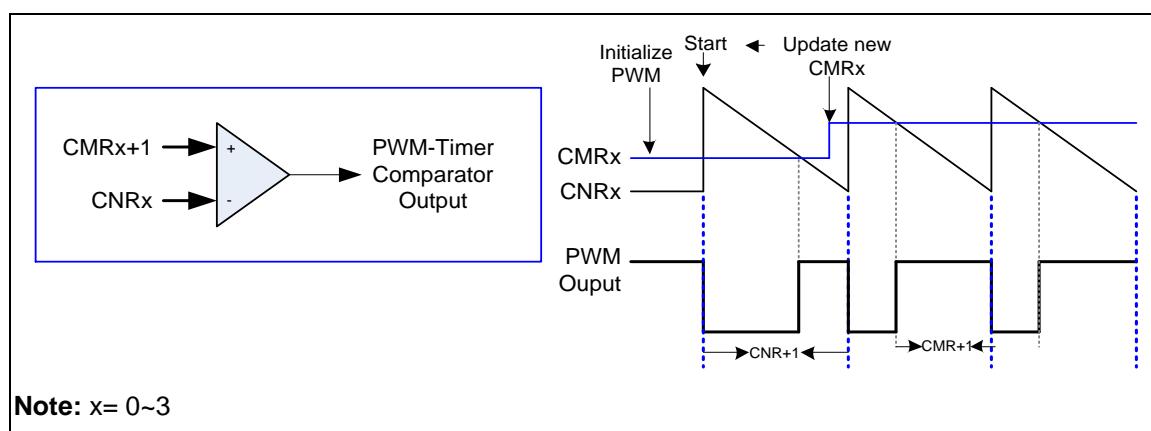

Figure 6-40 Legend of Internal Comparator Output of PWM-Timer

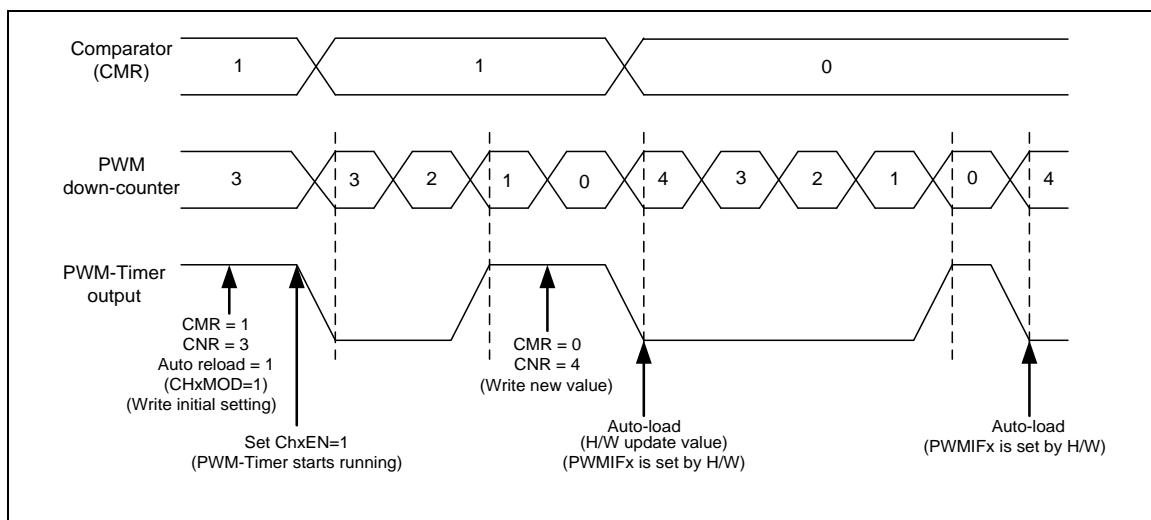

Figure 6-41 PWM Timer Operation Timing

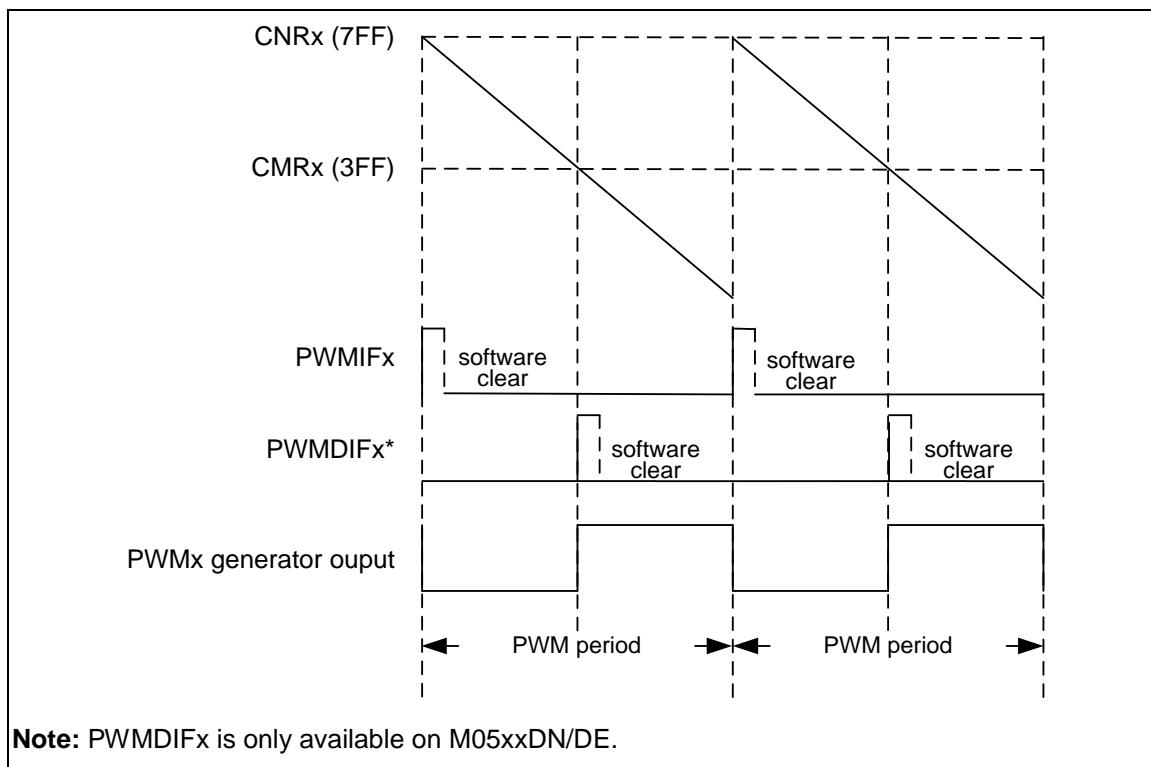

Figure 6-42 PWM Period Interrupt Generate Timing Waveform

Center-aligned PWM (Up/Down-counter) (M05xxDN/DE Only)

The center-aligned PWM signals are produced by the module when the PWM time base is configured in an Up/Down Counting mode. The PWM counter will start counting-up from 0 to match the value of CMRx (old); this will cause the toggling of the PWMx generator output

to low. The counter will continue counting to match with the CNRx (old). Upon reaching this state counter is configured automatically to down counting, when PWM counter matches the CMRx (old) value again the PWMx generator output toggles to high. Once the PWM counter underflows it will update the PWM period register CNRx(new) and duty cycle register CMRx(new) with CHxMODE = 1.

- PWM frequency = $\text{PWMxy_CLK}/[(\text{prescale}+1)*(\text{clock divider})*(\text{CNR}+1)]$; where xy, could be 01, 23, 45 or 67, depends on selected PWM channel.
- Duty ratio = $[(2 \times \text{CMR}) + 1]/[2 \times (\text{CNR}+1)]$
- CMR > CNR: PWM output is always high
- CMR <= CNR: PWM low width= $2 \times (\text{CNR}-\text{CMR}) + 1$ unit^[1]; PWM high width = $(2 \times \text{CMR}) + 1$ unit
- CMR = 0: PWM low width = $2 \times \text{CNR} + 1$ unit; PWM high width = 1 unit

Note [1]: unit = one PWM clock cycle.

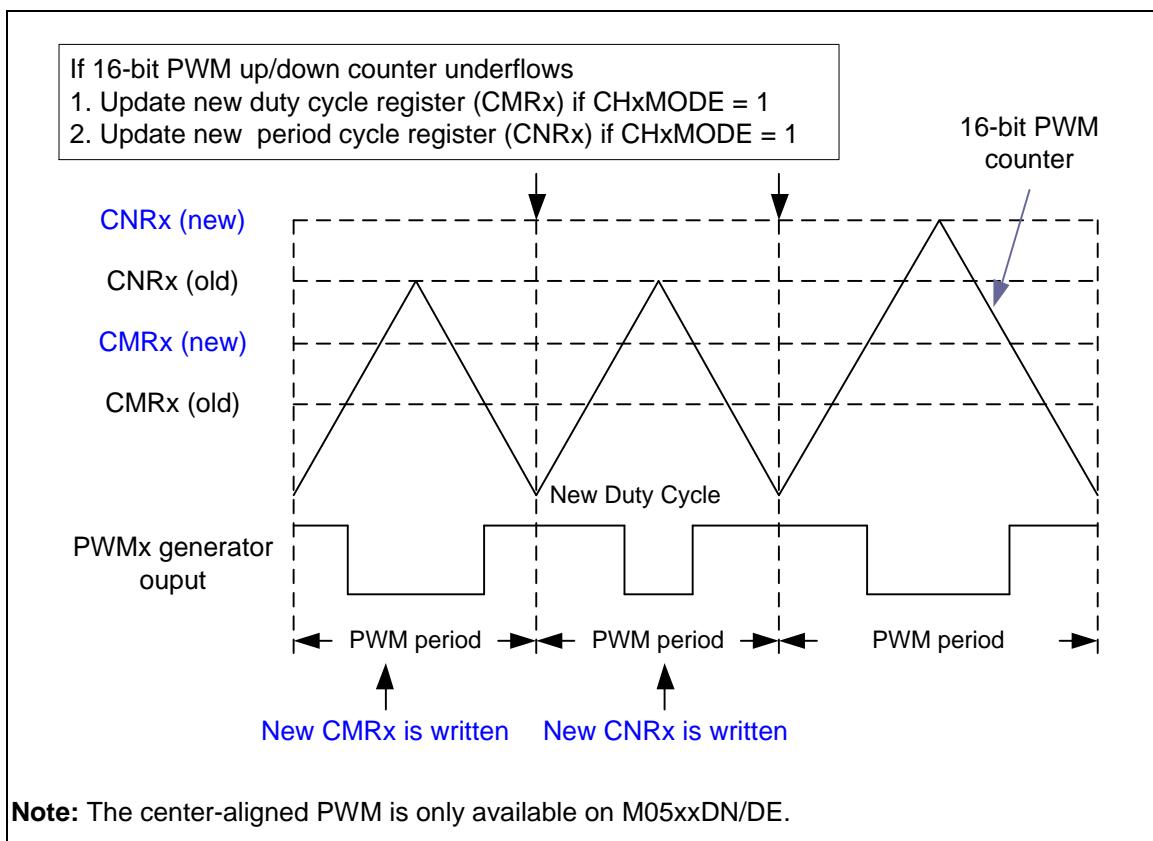

Figure 6-43 Center-aligned type Output Waveform

In Center-aligned type, system can generate two kinds of interrupt, period interrupt and duty interrupt, at four specified timings. PWM period interrupt is generated at counter equals zero on down-count if INTxxTYPE (PIER[17:16]) = 0 or at counter equals CNRx on up-count if INTxxTYPE (PIER[17:16]) = 1, i.e. at center point of PWM cycle. PWM duty interrupt is requested at counter equals CMR on down-count if INTxxDTYPE (PIER[25:24] = 0) or at counter equals CMR on up-count if INTxxDTYPE (PIER[25:24] = 1)

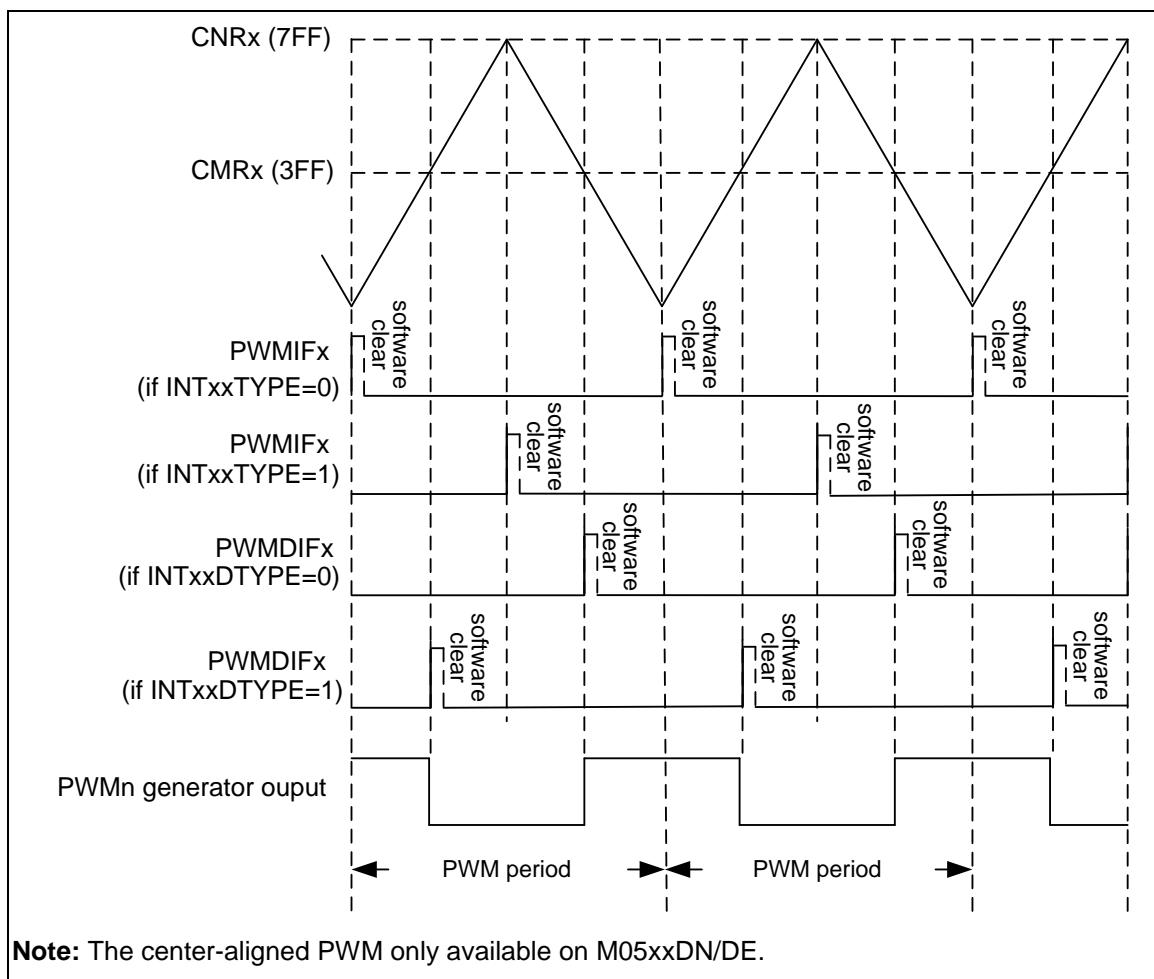

Figure 6-44 PWM Center-aligned Interrupt Generate Timing Waveform

6.8.5.2 PWM Double Buffering, Auto-reload and One-shot Operation

PWM Timers have double buffering function and the reload value is updated at the start of next period without affecting current timer operation. The PWM counter value can be written into CNRx and current PWM counter value can be read from PDRx.

PWM0 will operate in One-shot mode if CH0MOD bit is set to 0, and operate in Auto-reload mode if CH0MOD bit is set to 1. It is recommend that switch PWM0 operating mode before set CH0EN bit to 1 to enable PWM0 counter start running because the content of CNR0 and CMR0 will be cleared to 0 to reset the PWM0 period and duty setting when PWM0 operating mode is changed. As PWM0 operate in One-shot mode, CMR0 and CNR0 should be written first and then set CH0EN bit to 1 to enable PWM0 counter start running. After PWM0 counter down count from CNR0 value to 0, CNR0 and CMR0 will be cleared to 0 by hardware and PWM counter will be held. Software need to write new CMR0 and CNR0 value to set next one-shot period and duty. When re-start next one-shot operation, the CMR0 should be written first because PWM0 counter will auto re-start counting when CNR0 is written a non-zero value. As PWM0 operates at auto-reload mode, CMR0 and CNR0 should be written first and then set CH0EN bit to 1 to enable PWM0 counter start running. The value of CNR0 will reload to PWM0 counter when it down count reaches 0. If CNR0 is set to 0, PWM0 counter will be held. PWM1~PWM7 performs the same function as PWM0.

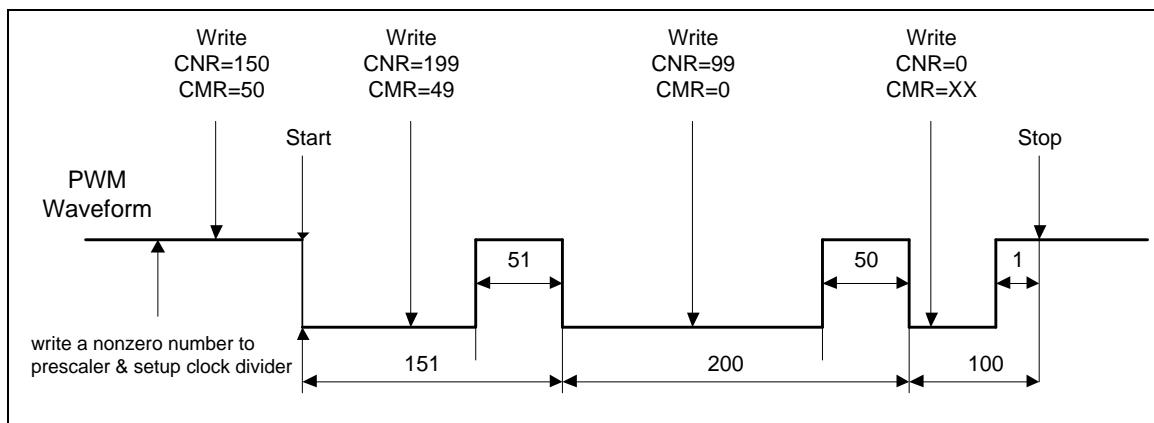

Figure 6-45 PWM Double Buffering Illustration

6.8.5.3 Modulate Duty Ratio

The double buffering function allows CMRx to be written at any point in current cycle. The loaded value will take effect from the next cycle.

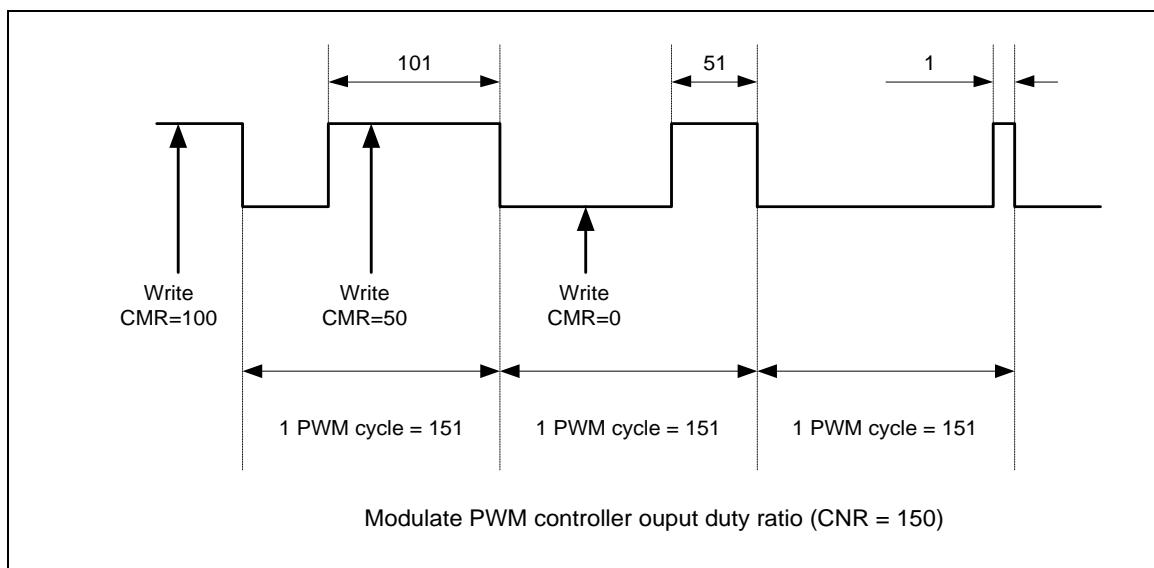

Figure 6-46 PWM Controller Output Duty Ratio

6.8.5.4 Dead-Zone Generator

The PWM controller is implemented with Dead-zone generator. They are built for power device protection. This function generates a programmable time gap to delay PWM rising output. User can program PPRx.DZI to determine the Dead-zone interval.

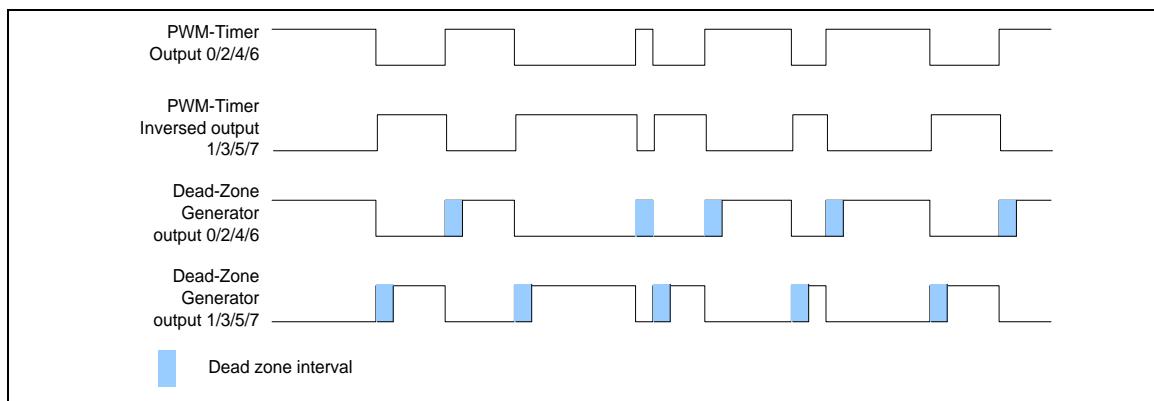

Figure 6-47 Paired-PWM Output with Dead-zone Generation Operation

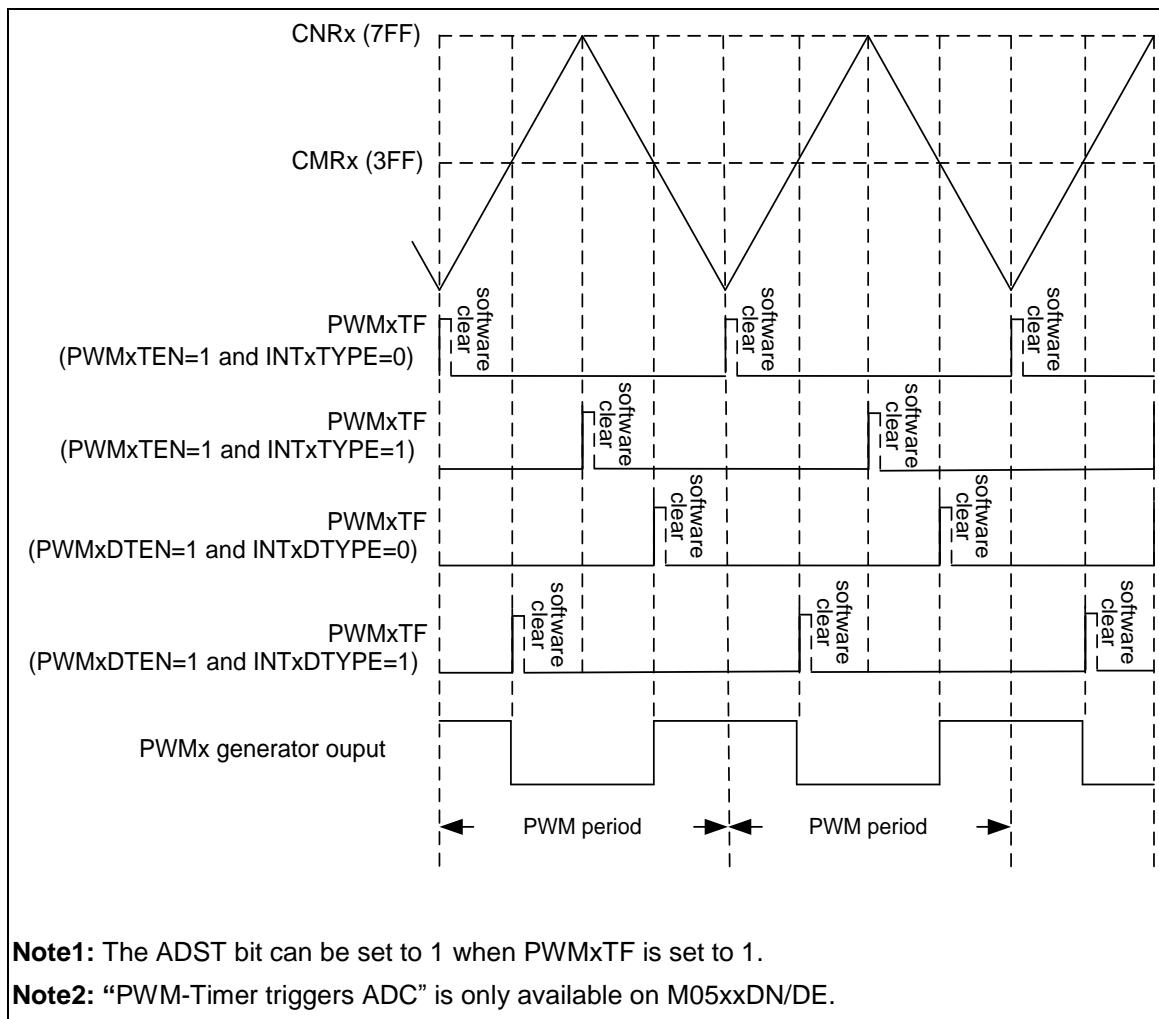

6.8.5.5 PWM-Timer Trigger ADC to Start Conversion (M05xxDN/DE Only)

PWM can be one of the ADC conversion trigger source. When PWM operating at center aligned type, four PWM trigger ADC-to-Conversion timings can be selected. When PWM operating at edge-aligned type, two PWM trigger ADC-to-Conversion timings can be selected.

For Center-aligned type, PWM can trigger ADC to start conversion in different timings by setting INTxxDTYPE/ INTxxTYPE and PWMxDTEN/ PWMxTEN. Trigger ADC timings and settings as shown below.

INTxxTEN	INTxxTYPE	Description
1	0	PWM counter equals to 0 at down-counting
1	1	PWM counter equal to CNRx + 1 at up-counting

INTxxDTEN	INTxxDTYPE	Description
1	0	PWM counter equals CMRx at down-counting
1	1	PWM counter equals CMRx at up-counting

Note1: The ADST bit can be set to 1 when PWMxTF is set to 1.

Note2: “PWM-Timer triggers ADC” is only available on M05xxDN/DE.

Figure 6-48 PWM Trigger ADC Flag (PWMxTF) in Center-aligned Type Timing Waveform

For Edge-aligned type, PWM can trigger ADC to start conversion in different timings by setting PWMxDTEN/ PWMxTEN. Trigger ADC timings and settings as shown below.

INTxDTEN	Description
1	PWM counter equals CMRx at down-counting
INTxTEN	Description
1	PWM counter equals to 0 at down-counting

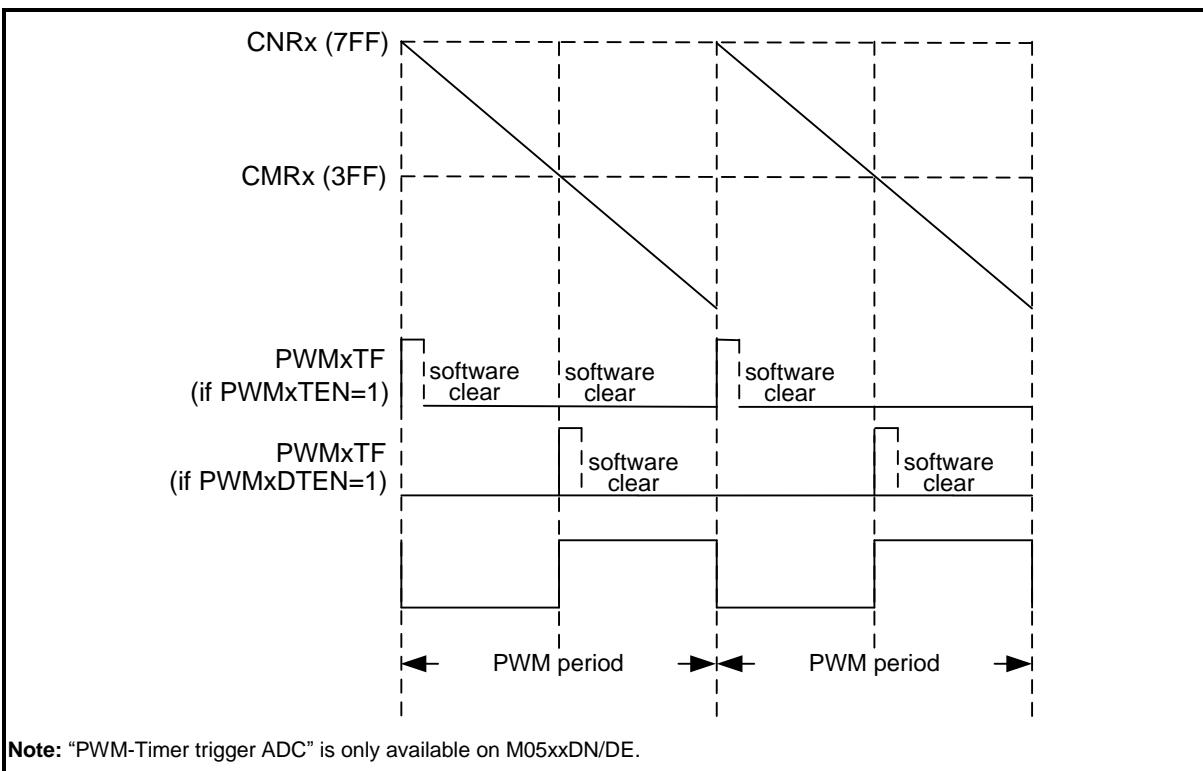

Figure 6-49 PWM Trigger ADC Flag (PWMxTF) in Edge-aligned Type Timing Waveform

6.8.5.6 PWM trigger ADC start-of-conversion procedure (M05xxDN/DE Only)

1. Configure prescaler register (PPRx) for setting clock prescaler (CPxx).
2. Configure clock select register (CSR_x) for setting clock source divider selection (CSR_x).
3. Configure PWM control register (PCR_x) for setting auto-reload mode (CH_xMOD = 1), PWM aligned type (PWM_{xx}TYPE) and DISABLE PWM-Timer (CH_xEN = 0).
4. Configure PWM control register (PCR_x) for setting inverter on/off (CH_xINV), polar inverse on/off (CH_xPINV) and Dead-zone generator on/off (DZEN_{xx}). (optional)
5. Configure PWM interrupt enable register (PIER) for setting PWM period interrupt type (INT_{xx}TYPE) and PWM duty interrupt type (INT_{xx}DTYPE).
6. Configure PWM trigger control register (TCON) to enable/disable PWM period trigger ADC (PWM_xTEN) and PWM duty trigger ADC (PWM_xDTEN).
7. Configure comparator register (CMRx) for setting PWM duty (CMRx).
8. Configure PWM counter register (CNRx) for setting PWM-Timer loaded value (CNRx).
9. Configure PWM output enable register (POE) to enable PWM output channel (PWM_x = 1)
10. Configure ADC trigger delay control register (ADTDCR) in ADC controller registers for setting PWM trigger delay time (PTDT) (optional)
11. Configure ADC channel enable register (ADCHER) in ADC controller registers to enable analog input channel (CHEN_x = 1)
12. Configure ADC control register (ADCR) in ADC controller registers for setting hardware trigger source is from PWM trigger (TRGS = 3), external trigger enable (TRGEN = 1), A/D converter operation mode (ADMD = 0,2,3) and A/D converter enable (ADEN = 1)

13. Configure PWM control register (PCR) to enable PWM timer start running ($CHxEN = 1$)
14. ADST (ADCR[11]) bit will be set to 1 by hardware when PWM trigger flag (PWMxTF) is set to 1 by hardware.
15. Software can poll A/D conversion end flag – ADF (ADSR[0]) to check if the conversion is finished or not.
16. ADST (ADCR[11]) bit will be cleared to 0 automatically in single mode and single cycle scan mode. In continuous scan mode, the ADST bit will keep 1 until software clears it.

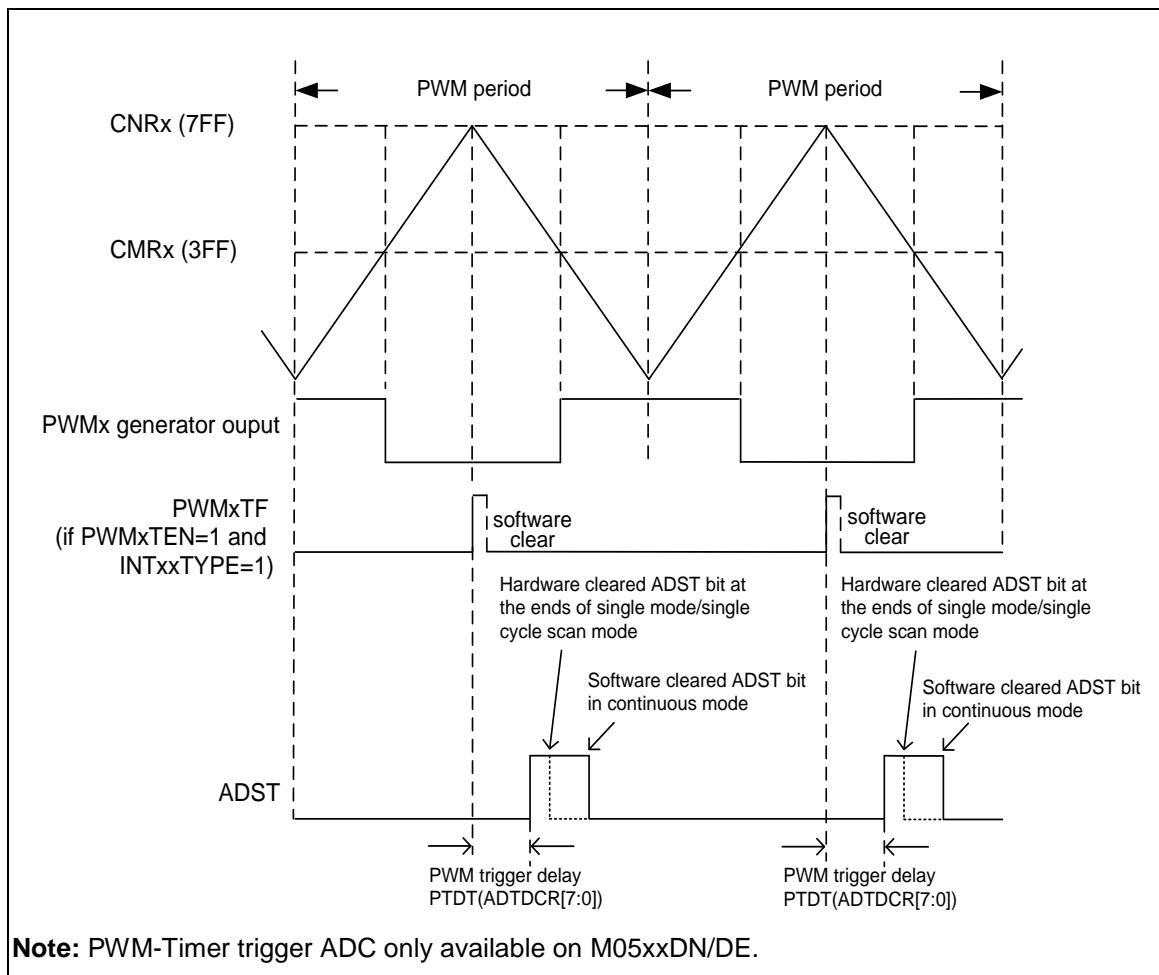

Figure 6-50 PWM Trigger ADC Start-of-Conversion in Center-aligned Type

6.8.5.7 Capture Operation

The Capture 0 and PWM 0 share one timer that included in PWM 0; and the Capture 1 and PWM 1 share another timer, and etc. The capture always latches PWM-counter to CRLRx when input channel has a rising transition and latches PWM-counter to CFLRx when input channel has a falling transition. Capture channel 0 interrupt is programmable by setting CCR0[1] (Rising latch Interrupt enable) and CCR0[2] (Falling latch Interrupt enable) to decide the condition of interrupt occur. Capture channel 1 has the same feature by setting CCR0[17] and CCR0[18], and etc. Whenever the Capture controller issues a capture interrupt, the corresponding PWM counter will be reloaded with CNRx at this moment. Note that the corresponding GPIO pins must be configured as capture function (POE disabled and CAPENR enabled) for the corresponding capture channel.

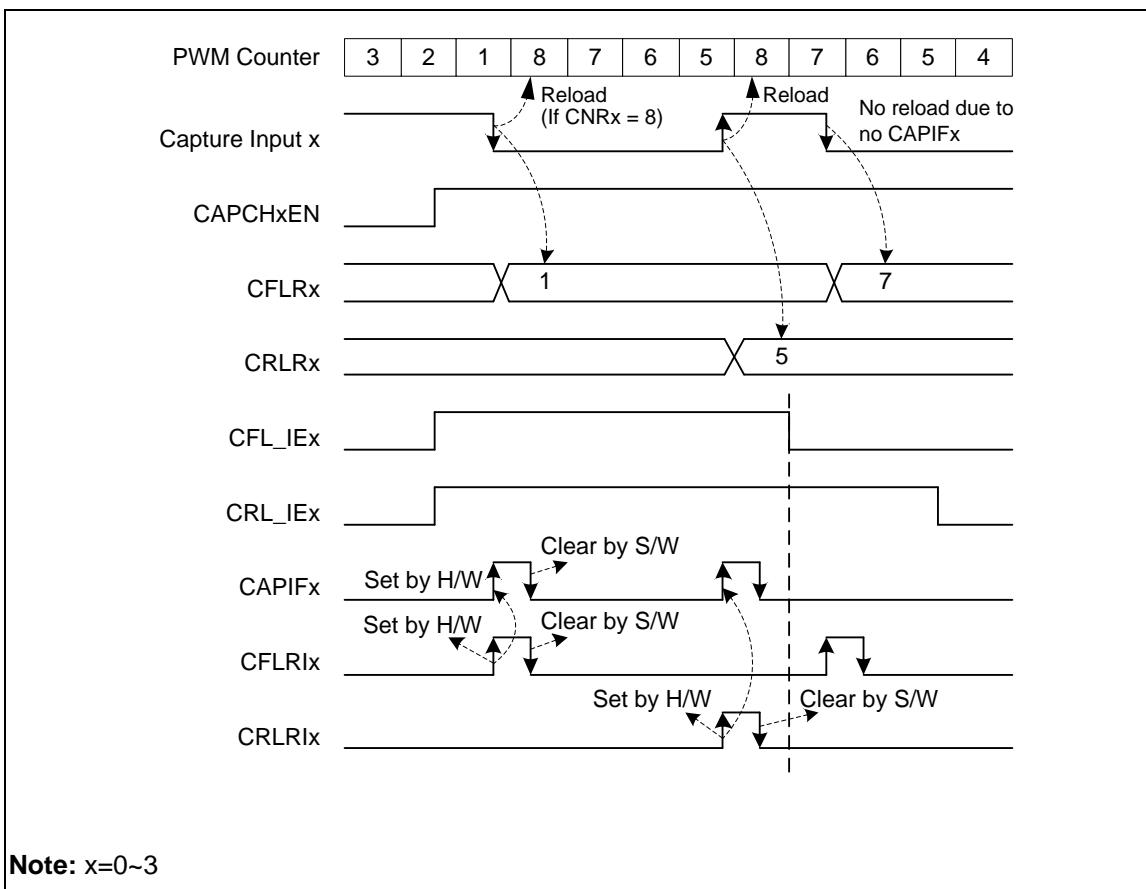

Figure 6-51 Capture Operation Timing

In this case, the CNR is 8:

1. The PWM counter will be reloaded with CNRx when a capture interrupt flag (CAPIFx) is set.
2. The channel low pulse width is (CNR + 1 – CRLR).
3. The channel high pulse width is (CNR + 1 – CFLR).

6.8.5.8 PWM-Timer Interrupt Architecture

There are eight PWM interrupts, PWM0_INT~PWM7_INT, which are divided into PWMA_INT and

PWMB_INT for Advanced Interrupt Controller (AIC). PWM 0 and Capture 0 share one interrupt, PWM1 and Capture 1 share the same interrupt and so on. Therefore, PWM function and Capture function in the same channel cannot be used at the same time. The following figure demonstrates the architecture of PWM-Timer interrupts.

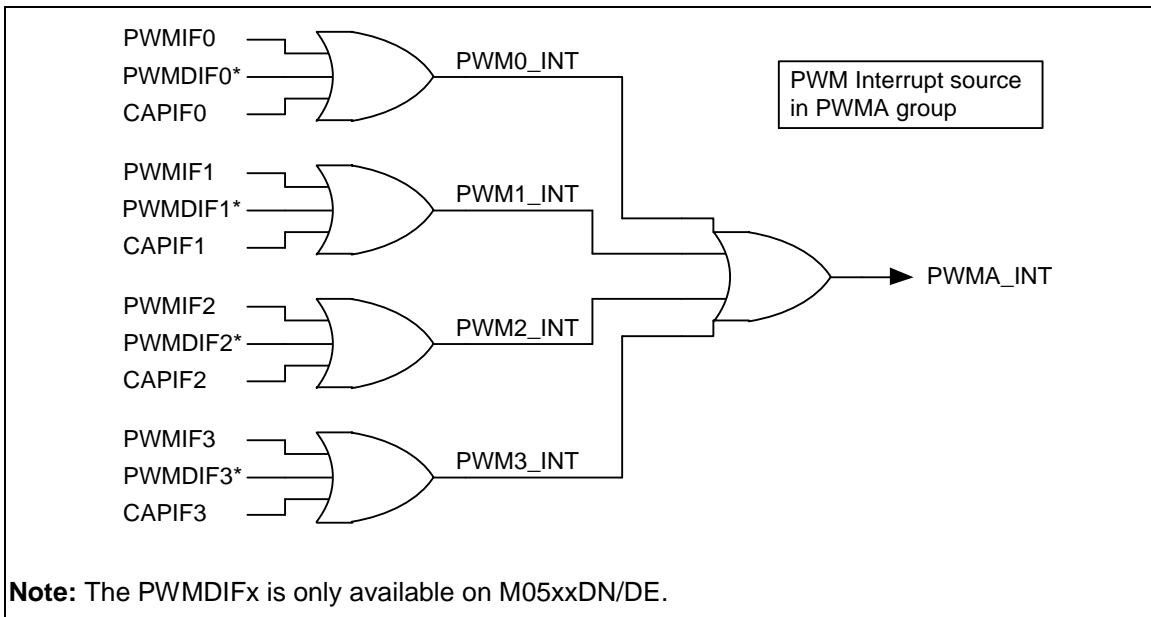

Figure 6-52 PWM Group A PWM-Timer Interrupt Architecture Diagram

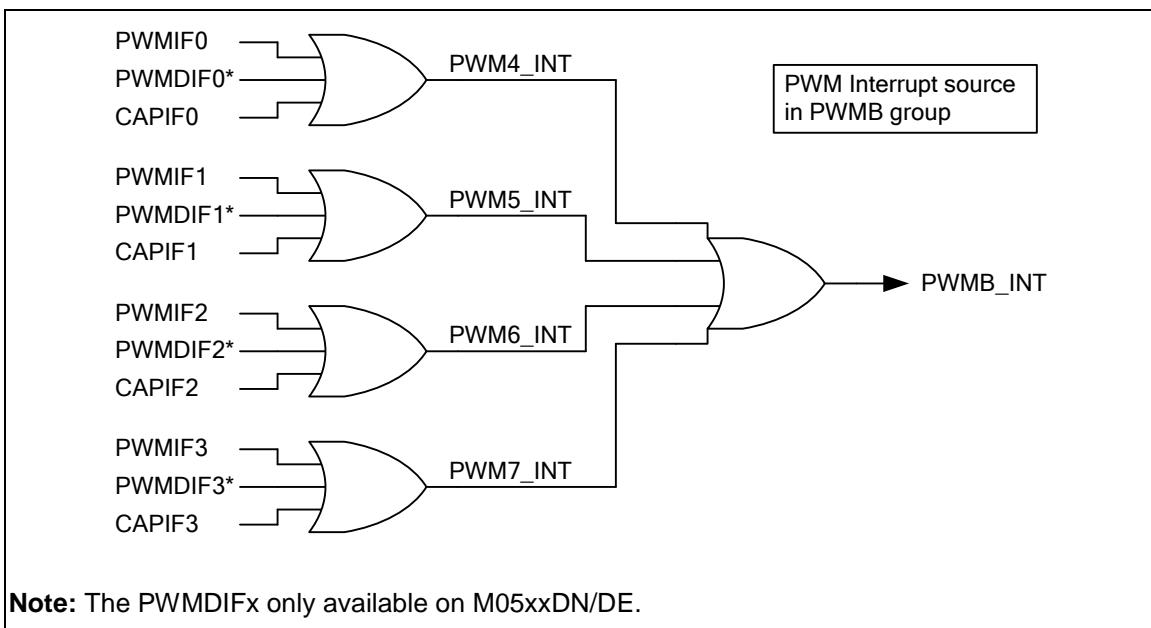

Figure 6-53 PWM Group B PWM-Timer Interrupt Architecture Diagram

6.8.5.9 PWM-Timer Start Procedure

The following procedure is recommended for starting a PWM drive.

1. Configure prescaler register (PPR) for setting clock prescaler (CPxx).
2. Configure clock select register (CSR) for setting clock source select (CSR_x).
3. Configure PWM control register (PCR) for setting auto-reload mode (CH_xMOD = 1) and DISABLE PWM-Timer (CH_xEN = 0).
4. Configure PWM control register (PCR) for setting inverter on/off (CH_xINV) and Dead-zone generator on/off (DZEN_{xx}). (optional)
5. Configure comparator register (CMRx) for setting PWM duty (CMRx).
6. Configure PWM counter register (CNRx) for setting PWM-Timer loaded value (CNRx).
7. Configure PWM interrupt enable register (PIER) for setting PWM period interrupt enable bit (PWMIE_x). (optional)
8. Configure PWM output enable register (POE) to enable PWM output channel (PWM_x = 1)
9. Configure PWM control register (PCR) to enable PWM timer start running (CH_xEN = 1)

6.8.5.10 PWM-Timer Re-Start Procedure in One-shot mode

After PWM waveform is generated once in PWM One-shot mode, PWM-Timer will be stopped automatically and both of CNRx and CMRx will be cleared by hardware. Software must fill CMRx and CNRx value again to re-start another PWM one-shot waveform. The following procedure is recommended for re-starting PWM one-shot waveform.

1. Configure comparator register (CMRx) for setting PWM duty (CMRx).
2. Configure PWM counter register (CNRx) for setting PWM period (CNRx). After setup CNRx, PWM wave will be generated.

6.8.5.11 PWM-Timer Stop Procedure

Method 1:

Set 16-bit counter register (CNRx) as 0, and monitor data register (PDRx, current value of 16-bit down-counter). When PDRx reaches to 0, disable PWM-Timer (CH_xEN in PCR). (*Recommended*)

Method 2:

Set 16-bit counter register (CNRx) as 0. When interrupt request happened, disable PWM-Timer (CH_xEN in PCR). (*Recommended*)

Method 3:

Disable PWM-Timer directly (CH_xEN in PCR) (*Not recommended*)

The reason why method 3 is not recommended is that disabling CH_xEN will immediately stop PWM output signal and lead to change the duty of the PWM output, this may cause damage to the control circuit of motor.

6.8.5.12 PWM-Timer Synchronous Start Procedure

Group a PWM-Timer1~3 and group B PWM-Timer0~3 can synchronous start with group A PWM-Time0. The following procedure is recommended for PWM-Timer synchronous start

1. Configure prescaler register (PPR) for setting clock prescaler (CPxx).
2. Configure clock select register (CSR) for setting clock source select (CSR_x).
3. Configure PWM control register (PCR) for setting inverter auto-reload mode (CH_xMOD = 1), PWM aligned type (PWM_{xx}TYPE) and DISABLE PWM-Timer (CH_xEN = 0).
4. Configure PWM control register (PCR) for setting inverter on/off (CH_xINV), polar inverse on/off (CH_xPINV) and Dead-zone generator on/off (DZEN_n). (optional)
5. Configure comparator register (CMRx) for setting PWM duty (CMRx).
6. Configure PWM counter register (CNRx) for setting PWM-Timer loaded value (CNRx).
7. Configure PWM interrupt enable register (PIER) for setting PWM period interrupt type (INT_{xx}TYPE), PWM duty interrupt type (INT_{xx}DTYPE), PWM period interrupt enable bit (PWMIEx) and PWM duty interrupt enable bit (PWMDIEx). (optional)
8. Configure PWM output enable register (POE) to enable PWM output channel (PWM_x)
9. Configure PWM synchronous control register (PSCR) to enable PWM synchronous start bit (PSSEN_x = 1)
10. Configure group A PWM control register (PCR) to enable group A PWM-Timer0 start running (CH0EN = 1 in group A PCR). All of specified PWM-Timers will synchronous start with group A PWM-Timer0.

6.8.5.13 Capture Start Procedure

1. Configure prescaler register (PPR) for setting clock prescaler (CPxx).
2. Configure clock select register (CSR) for setting clock source select (CSR_x)
3. Configure PWM control register (PCR) for setting auto-reload mode (CH_xMOD = 1) and DISABLE PWM-Timer (CH_xEN = 0).
4. Configure PWM capture control register (CCRx) for setting rising interrupt enable (CRL_IEx), falling interrupt enable (CFL_IEx) and input signal inverter on/off (INV_x)
5. Configure PWM counter register (CNRx) for setting PWM-Timer loaded value (CNRx).
6. Configure PWM control register (PCR) to enable PWM timer start running (CH_xEN = 1)
7. Configure the capture input channel enable register (CAPENR) to enable the corresponding GPIO pins as capture function.

6.8.7 Register Description

PWM Prescaler Register (PPR)

Register	Offset	R/W	Description	Reset Value
PPR	PWMA_BA+0x00 PWMB_BA+0x00	R/W	PWM Prescaler Register	0x0000_0000

31	30	29	28	27	26	25	24
DZI23							
23	22	21	20	19	18	17	16
DZI01							
15	14	13	12	11	10	9	8
CP23							
7	6	5	4	3	2	1	0
CP01							

Bits	Description	
[31:24]	DZI23	Dead-zone Interval for Pair of Channel 2 and Channel 3 (PWM2 and PWM3 Pair for PWM Group A, PWM6 and PWM7 Pair for PWM Group B) These 8-bit determine the Dead-zone length. The unit time of Dead-zone length = [(prescale+1)*(clock source divider)]/ PWMxy_CLK (where xy could be 23 or 67, depends on selected PWM channel.).
[23:16]	DZI01	Dead-zone Interval for Pair of Channel 0 and Channel 1 (PWM0 and PWM1 Pair for PWM Group A, PWM4 and PWM5 Pair for PWM Group B) These 8-bit determine the Dead-zone length. The unit time of Dead-zone length = [(prescale+1)*(clock source divider)]/ PWMxy_CLK (where xy could be 01 or 45, depends on selected PWM channel.).
[15:8]	CP23	Clock Prescaler 2 (PWM-timer 2 / 3 for Group A and PWM-timer 6 / 7 for Group B) Clock input is divided by (CP23 + 1) before it is fed to the corresponding PWM-Timer. If CP23=0, then the clock prescaler 2 output clock will be stopped. So corresponding PWM-Timer will also be stopped.
[7:0]	CP01	Clock Prescaler 0 (PWM-timer 0 / 1 for Group A and PWM-timer 4 / 5 for Group B) Clock input is divided by (CP01 + 1) before it is fed to the corresponding PWM-Timer. If CP01=0, then the clock prescaler 0 output clock will be stopped. So corresponding PWM-Timer will also be stopped.

PWM Clock Selector Register (CSR)

Register	Offset	R/W	Description				Reset Value
CSR	PWMA_BA+0x04 PWMB_BA+0x04	R/W	PWM Clock Source Divider Select Register				0x0000_0000

Bits	Description	
[31]	PWM23TYPE	PWM23 Aligned Type Selection Bit (PWM2 and PWM3 Pair for PWM Group A, PWM6 and PWM7 Pair for PWM Group B) (M05xxDN/DE Only) 0 = Edge-aligned type. 1 = Center-aligned type.
[30]	PWM01TYPE	PWM01 Aligned Type Selection Bit (PWM0 and PWM1 Pair for PWM Group A, PWM4 and PWM5 Pair for PWM Group B) (M05xxDN/DE Only) 0 = Edge-aligned type. 1 = Center-aligned type.
[29:28]	Reserved	Reserved.
[27]	CH3MOD	PWM-timer 3 Auto-reload/One-shot Mode Control (PWM Timer 3 for Group A and PWM Timer 7 for Group B) 0 = One-shot mode. 1 = Auto-reload mode. Note: If there is a transition at this bit, it will cause CNR3 and CMR3 be cleared.
[26]	CH3INV	PWM-timer 3 Output Inverter Enable Control (PWM Timer 3 for Group A and PWM Timer 7 for Group B) 0 = Inverter Disabled. 1 = Inverter Enabled.
[25]	CH3PINV	PWM-timer 3 Output Polar Inverse Enable Control (PWM Timer 3 for Group A and PWM Timer 7 for Group B) (M05xxDN/DE Only) 0 = Polar Inverter Disabled. 1 = Polar Inverter Enabled.
[24]	CH3EN	PWM-timer 3 Enable Control (PWM Timer 3 for Group A and PWM Timer 7 for Group B) 0 = Corresponding PWM-Timer Stopped. 1 = Corresponding PWM-Timer Start Running.
[23:20]	Reserved	Reserved.

[19]	CH2MOD	PWM-timer 2 Auto-reload/One-shot Mode Control (PWM Timer 2 for Group A and PWM Timer 6 for Group B) 0 = One-shot mode. 1 = Auto-reload mode. Note: If there is a transition at this bit, it will cause CNR2 and CMR2 be cleared.
[18]	CH2INV	PWM-timer 2 Output Inverter Enable Control (PWM Timer 2 for Group A and PWM Timer 6 for Group B) 0 = Inverter Disabled. 1 = Inverter Enabled.
[17]	CH2PINV	PWM-timer 2 Output Polar Inverse Enable (PWM Timer 2 for Group A and PWM Timer 6 for Group B) (M05xxDN/DE Only) 0 = Polar Inverter Disabled. 1 = Polar Inverter Enabled.
[16]	CH2EN	PWM-timer 2 Enable (PWM Timer 2 for Group A and PWM Timer 6 for Group B) 0 = Corresponding PWM-Timer Stopped. 1 = Corresponding PWM-Timer Start Running.
[15:12]	Reserved	Reserved.
[11]	CH1MOD	PWM-timer 1 Auto-reload/One-shot Mode (PWM Timer 1 for Group A and PWM Timer 5 for Group B) 0 = One-shot mode. 1 = Auto-reload mode. Note: If there is a transition at this bit, it will cause CNR1 and CMR1 be cleared.
[10]	CH1INV	PWM-timer 1 Output Inverter Enable (PWM Timer 1 for Group A and PWM Timer 5 for Group B) 0 = Inverter Disabled. 1 = Inverter Enabled.
[9]	CH1PINV	PWM-timer 1 Output Polar Inverse Enable (PWM Timer 1 for Group A and PWM Timer 5 for Group B) (M05xxDN/DE Only) 0 = Polar Inverter Disabled. 1 = Polar Inverter Enabled.
[8]	CH1EN	PWM-timer 1 Enable (PWM Timer 1 for Group A and PWM Timer 5 for Group B) 0 = Corresponding PWM-Timer Stopped. 1 = Corresponding PWM-Timer Start Running.
[7:6]	Reserved	Reserved.
[5]	DZEN23	Dead-zone 2 Generator Enable (PWM2 and PWM3 Pair for PWM Group A, PWM6 and PWM7 Pair for PWM Group B) 0 = Disabled. 1 = Enabled. Note: When Dead-zone generator is enabled, the pair of PWM2 and PWM3 becomes a complementary pair for PWM group A and the pair of PWM6 and PWM7 becomes a complementary pair for PWM group B.
[4]	DZEN01	Dead-zone 0 Generator Enable Control (PWM0 and PWM1 Pair for PWM Group A, PWM4 and PWM5 Pair for PWM Group B) 0 = Disabled. 1 = Enabled. Note: When Dead-zone generator is enabled, the pair of PWM0 and PWM1 becomes a complementary pair for PWM group A and the pair of PWM4 and PWM5 becomes a complementary pair for PWM group B.

[3]	CH0MOD	PWM-timer 0 Auto-reload/One-shot Mode Control (PWM Timer 0 for Group A and PWM Timer 4 for Group B) 0 = One-shot mode. 1 = Auto-reload mode. Note: If there is a transition at this bit, it will cause CNR0 and CMR0 be cleared.
[2]	CH0INV	PWM-timer 0 Output Inverter Enable Control (PWM Timer 0 for Group A and PWM Timer 4 for Group B) 0 = Inverter Disabled. 1 = Inverter Enabled.
[1]	CH0PINV	PWM-timer 0 Output Polar Inverse Enable Control (PWM Timer 0 for Group A and PWM Timer 4 for Group B) (M05xxDN/DE Only) 0 = Polar Inverter Disabled. 1 = Polar Inverter Enabled.
[0]	CH0EN	PWM-timer 0 Enable Control (PWM Timer 0 for Group A and PWM Timer 4 for Group B) 0 = The corresponding PWM-Timer stops running. 1 = The corresponding PWM-Timer starts running.

PWM Counter Register 3-0 (CNR3-0)

Register	Offset	R/W	Description	Reset Value
CNR0	PWMA_BA+0x0C PWMB_BA+0x0C	R/W	PWM Counter Register 0	0x0000_0000
CNR1	PWMA_BA+0x18 PWMB_BA+0x18	R/W	PWM Counter Register 1	0x0000_0000
CNR2	PWMA_BA+0x24 PWMB_BA+0x24	R/W	PWM Counter Register 2	0x0000_0000
CNR3	PWMA_BA+0x30 PWMB_BA+0x30	R/W	PWM Counter Register 3	0x0000_0000

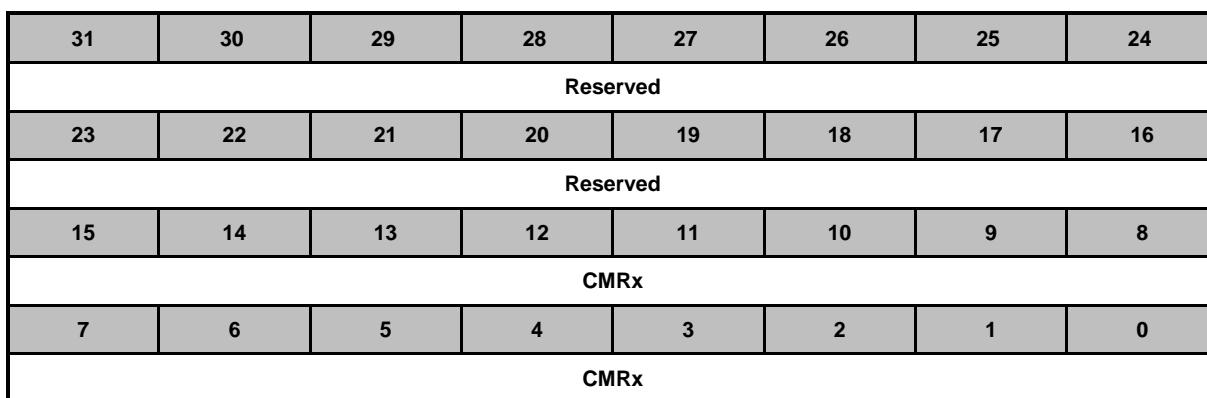

Bits	Description	
[31:16]	Reserved	Reserved.
[15:0]	CNRx	<p>PWM Timer Loaded Value CNR determines the PWM period. PWM frequency = PWMy_CLK/[(prescale+1)*(clock divider)*(CNR+1)]; where xy, could be 01, 23, 45 or 67, depends on selected PWM channel.</p> <p>For Edge-aligned Type:</p> <ul style="list-style-type: none"> • Duty ratio = (CMR+1)/(CNR+1). • CMR >= CNR: PWM output is always high. • CMR < CNR: PWM low width = (CNR-CMR) unit; PWM high width = (CMR+1) unit. • CMR = 0: PWM low width = (CNR) unit; PWM high width = 1 unit. <p>For Center-aligned Type (M05xxDN/DE Only):</p> <ul style="list-style-type: none"> • Duty ratio = [(2 x CMR) + 1]/[2 x (CNR+1)]. • CMR > CNR: PWM output is always high. • CMR <= CNR: PWM low width = 2 x (CNR-CMR) + 1 unit; PWM high width = (2 x CMR) + 1 unit. • CMR = 0: PWM low width = 2 x CNR + 1 unit; PWM high width = 1 unit. (Unit = one PWM clock cycle).

		<p>Note1: Any write operation to CNR will take effect in next PWM cycle.</p> <p>Note2: When CNR value is set to 0, PWM output is always high.</p> <p>Note3: When PWM operating at center-aligned type, CNR value should be set between 0x0001 to 0xFFFF. If CNR equal to 0x0000 or 0xFFFF, the PWM will work unpredictable.</p>

6.9 Watchdog Timer (WDT)

6.9.1 Overview

The purpose of Watchdog Timer is to perform a system reset when system runs into an unknown state. This prevents system from hanging for an infinite period of time. Besides, this Watchdog Timer supports the function to wake-up system from Idle/Power-down mode.

6.9.2 Features

- 18-bit free running up counter for Watchdog Timer time-out interval
- Selectable time-out interval ($2^4 \sim 2^{18}$) WDT_CLK cycle and the time-out interval period is 104 ms ~ 26.3168 s if WDT_CLK = 10 kHz
- System kept in reset state for a period of $(1 / \text{WDT_CLK}) * 63$
- Supports Watchdog Timer reset delay period
 - ◆ Fixed 1024 * WDT_CLK reset delay period on M05xxBN
 - ◆ Selectable reset delay period 3/18/130/1026 * WDT_CLK on M05xxDN/DE
- Supports to force Watchdog Timer enabled after chip powered on or reset while CWDTEN (CONFIG[31] Watchdog Enable) bit is set to 0. (M05xxDN/DE Only)
- Supports Watchdog Timer time-out wake-up function only if WDT clock source is selected as 10 kHz

6.9.3 Block Diagram

The Watchdog Timer clock control and block diagram are shown as follows.

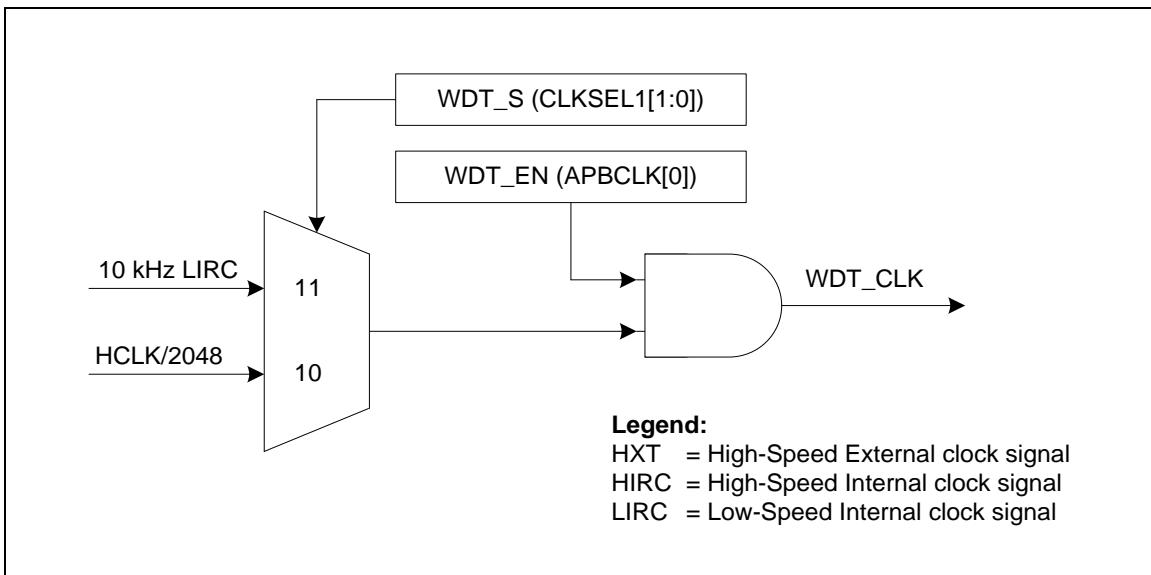

Figure 6-54 Watchdog Timer Clock Control

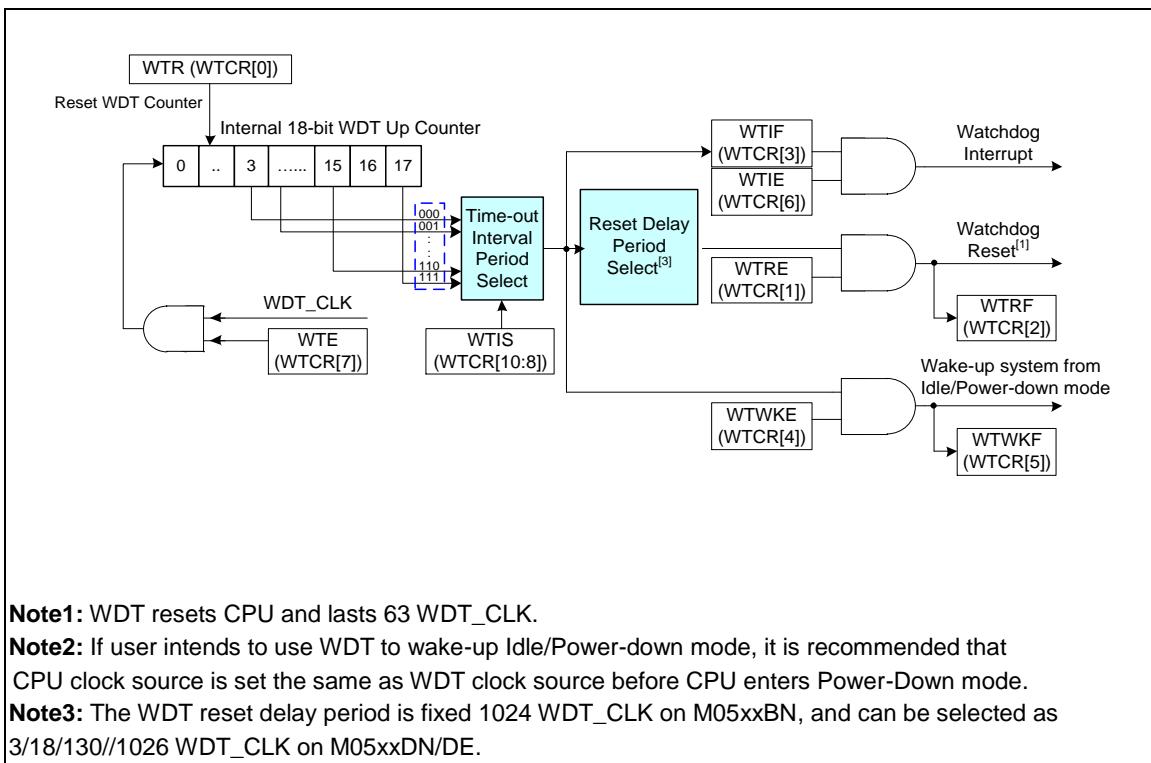

Figure 6-55 Watchdog Timer Block Diagram

6.9.4 Basic Configuration

The WDT peripheral clock is enabled in APBCLK[0] and clock source can be selected in CLKSEL1[1:0].

Or user can setting CONFIG[31] 0 to force Watchdog Timer enabled and active in 10 kHz after chip powered on or reset on M05xxDN/DE.

6.9.5 Functional Description

The Watchdog Timer (WDT) includes an 18-bit free running up counter with programmable time-out intervals. Table 6-21 shows the WDT time-out interval period selection and Figure 6-56 shows the WDT time-out interval and reset period timing.

WDT Time-out Interrupt

Setting WTE bit to 1 will enable the WDT function and the WDT counter to start counting up. There are eight time-out interval period can be selected by setting WTIS. When the WDT up counter reaches the WTIS settings, WDT time-out interrupt will occur then WTIF flag will be set to 1 immediately.

WDT Reset Delay Period and Reset System

There is a specified T_{RSTD} delay period follows the WTIF flag is setting to 1. User should set WTR bit to reset the 18-bit WDT up counter value to avoid generate WDT time-out reset signal before the T_{RSTD} delay period expires. If the WDT up counter value has not been cleared after the specific T_{RSTD} delay period expires, the WDT control will set WTRF flag to 1 if WTRE bit is enabled, then chip enters to reset state immediately. Refer to Figure 6-56, the T_{RST} reset period will keep last 63 WDT clocks then chip restart executing program from reset vector (0x0000_0000). The WTRF flag will keep 1 after WDT time-out reset the chip, user can check WTRF flag by software to recognize the system has been reset by WDT time-out reset or not.

WDT Wake-up

If WDT clock source is selected to 10 kHz, system can be waken-up from Power-down mode while WDT time-out interrupt signal is generated and WTWKE bit enabled. In the meanwhile, the WTWKF flag will set to 1 automatically, user can check WTWKF flag by software to recognize the system has been waken-up by WDT time-out interrupt or not.

WTIS	Time-Out Interval Period T_{TIS}	Reset Delay Period (M05xxBN)	
		T_{RSTD}	T_{RSTD}
000	$2^4 * T_{WDT}$	$1024 * T_{WDT}$	$(3/18/130/1026) * T_{WDT}$
001	$2^6 * T_{WDT}$	$1024 * T_{WDT}$	$(3/18/130/1026) * T_{WDT}$
010	$2^8 * T_{WDT}$	$1024 * T_{WDT}$	$(3/18/130/1026) * T_{WDT}$

[31]	DBGACK_WDT	ICE Debug Mode Acknowledge Disable Control (Write Protect) 0 = ICE debug mode acknowledgement effects WDT counting. WDT up counter will be held while CPU is held by ICE. 1 = ICE debug mode acknowledgement Disabled. WDT up counter will keep going no matter CPU is held by ICE or not.
[30:11]	Reserved	Reserved.
[10:8]	WTIS	Watchdog Timer Time-out Interval Selection (Write Protect) These three bits select the time-out interval period for the WDT. 000 = $2^4 * T_{WDT}$. 001 = $2^6 * T_{WDT}$. 010 = $2^8 * T_{WDT}$. 011 = $2^{10} * T_{WDT}$. 100 = $2^{12} * T_{WDT}$. 101 = $2^{14} * T_{WDT}$. 110 = $2^{16} * T_{WDT}$. 111 = $2^{18} * T_{WDT}$.
[7]	WTE	Watchdog Timer Enable Control (Write Protect) 0 = WDT Disabled. (This action will reset the internal up counter value.) 1 = WDT Enabled.
[6]	WTIE	Watchdog Timer Time-out Interrupt Enable Control (Write Protect) If this bit is enabled, the WDT time-out interrupt signal is generated and inform to CPU. 0 = WDT time-out interrupt Disabled. 1 = WDT time-out interrupt Enabled.
[5]	WTWKF	Watchdog Timer Time-out Wake-up Flag

		This bit indicates the interrupt wake-up flag status of WDT. 0 = WDT does not cause chip wake-up. 1 = Chip wake-up from Idle or Power-down mode if WDT time-out interrupt signal generated. Note: This bit is cleared by writing 1 to it.
[4]	WTWKE	Watchdog Timer Time-out Wake-up Function Control (Write Protect) If this bit is set to 1, while WTIF is generated to 1 and WTIE enabled, the WDT time-out interrupt signal will generate a wake-up trigger event to chip. 0 = Wake-up trigger event Disabled if WDT time-out interrupt signal generated. 1 = Wake-up trigger event Enabled if WDT time-out interrupt signal generated. Note: Chip can be woken-up by WDT time-out interrupt signal generated only if WDT clock source is selected to 10 kHz oscillator.
[3]	WTIF	Watchdog Timer Time-out Interrupt Flag This bit will set to 1 while WDT up counter value reaches the selected WDT time-out interval. 0 = WDT time-out interrupt did not occur. 1 = WDT time-out interrupt occurred. Note: This bit is cleared by writing 1 to it.
[2]	WTRF	Watchdog Timer Time-out Reset Flag This bit indicates the system has been reset by WDT time-out reset or not. 0 = WDT time-out reset did not occur. 1 = WDT time-out reset occurred. Note: This bit is cleared by writing 1 to it.
[1]	WTRE	Watchdog Timer Time-out Reset Enable Control (Write Protect) Setting this bit will enable the WDT time-out reset function If the WDT up counter value has not been cleared after the specific WDT reset delay period expires. 0 = WDT time-out reset function Disabled. 1 = WDT time-out reset function Enabled. Note: Fixed $1024 * T_{WDT}$ delay period on M05xxBN. Selectable 3/18/130/1026 * T_{WDT} delay period controlled by WTRDSEL on M05xxDE.
[0]	WTR	Reset Watchdog Timer Up Counter (Write Protect) 0 = No effect. 1 = Reset the internal 18-bit WDT up counter value. Note: This bit will be automatically cleared by hardware.

6.10 Window Watchdog Timer (WWDT) (M05xxDN/DE Only)

6.10.1 Overview

The Window Watchdog Timer is used to perform a system reset within a specified window period to prevent software run to uncontrollable status by any unpredictable condition.

6.10.2 Features

- 6-bit down counter value (WWDTVAL) and 6-bit compare window value (WINCMP) to make the WWDT time-out window period flexible
- Supports 4-bit value to programmable maximum 11-bit prescale counter period of WWDT counter

6.10.3 Block Diagram

The Window Watchdog Timer clock control and block diagram are shown as follows.

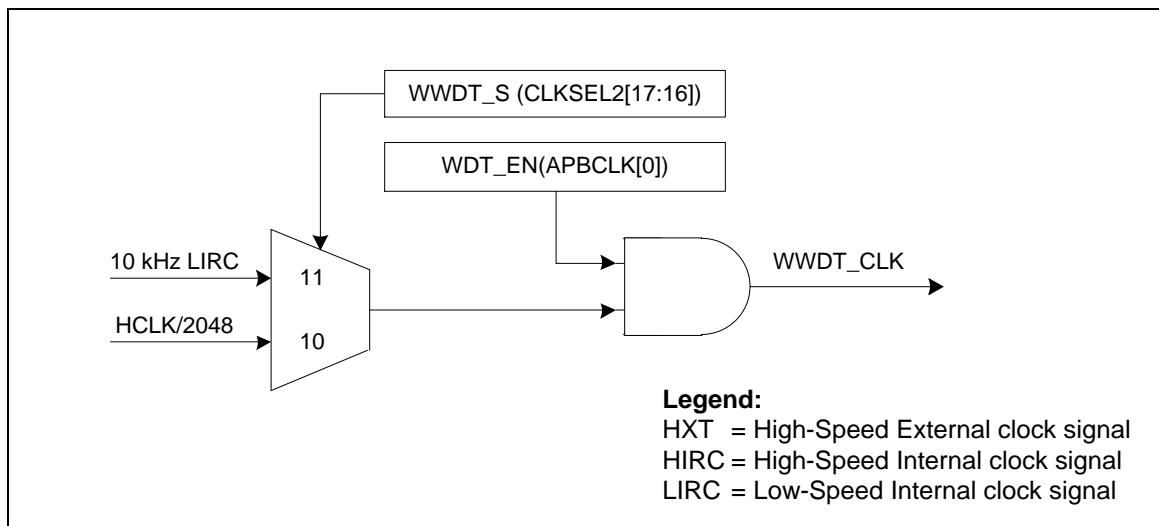

Figure 6-57 Window Watchdog Timer Clock Control

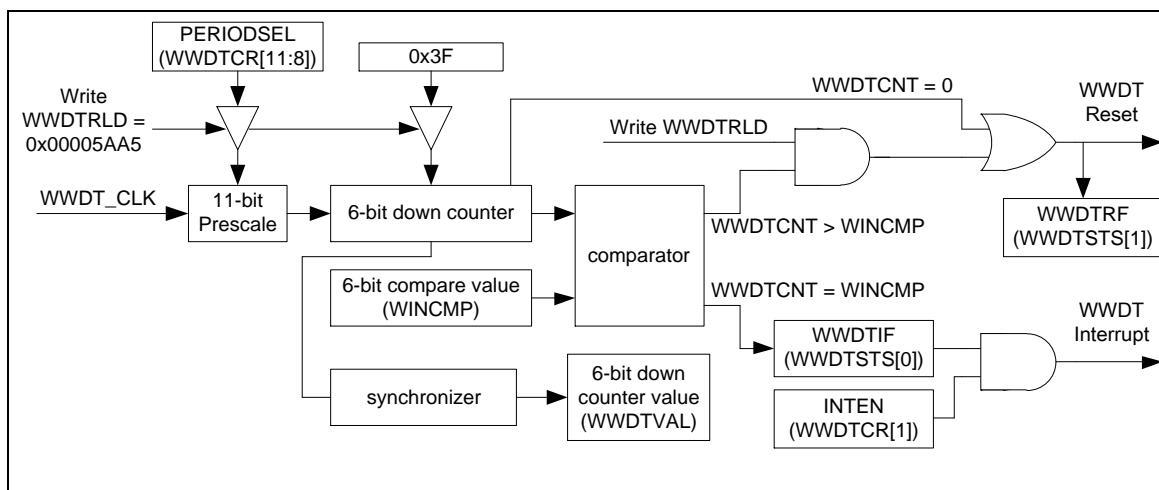

Figure 6-58 Window Watchdog Timer Block Diagram

6.10.4 Basic Configuration

The WWDT peripheral clock is enabled in APBCLK[0] and clock source can be selected in CLKSEL2[17:16].

6.10.5 Functional Description

The Window Watchdog Timer (WWDT) includes a 6-bit down counter with programmable prescale value to define different WWDT time-out intervals. The clock source of 6-bit WWDT is based on system clock divide 2048 (HCLK/2048) or internal 10 kHz oscillator with a programmable 11-bit prescale counter value which controlled by PERIODSEL setting. Also, the correlate of PERIODSEL and prescale value are listed in the following table.

PERIODSEL	Prescale Value	Max. Time-Out Period	Max. Time-Out Interval (WWDT_CLK=10 KHz)
0000	1	$1 * 64 * T_{WWDT}$	6.4 ms
0001	2	$2 * 64 * T_{WWDT}$	12.8 ms
0010	4	$4 * 64 * T_{WWDT}$	25.6 ms
0011	8	$8 * 64 * T_{WWDT}$	51.2 ms
0100	16	$16 * 64 * T_{WWDT}$	102.4 ms
0101	32	$32 * 64 * T_{WWDT}$	204.8 ms
0110	64	$64 * 64 * T_{WWDT}$	409.6 ms
0111	128	$128 * 64 * T_{WWDT}$	819.2 ms
1000	192	$192 * 64 * T_{WWDT}$	1.2288 s
1001	256	$256 * 64 * T_{WWDT}$	1.6384 s
1010	384	$384 * 64 * T_{WWDT}$	2.4576 s
1011	512	$512 * 64 * T_{WWDT}$	3.2768 s
1100	768	$768 * 64 * T_{WWDT}$	4.9152 s
1101	1024	$1024 * 64 * T_{WWDT}$	6.5536 s
1110	1536	$1536 * 64 * T_{WWDT}$	9.8304 s
1111	2048	$2048 * 64 * T_{WWDT}$	13.1072 s

Table 6-12 Window Watchdog Timer Prescale Value Selection

WWDT Counting

When the WWDTEN bit is set, WWDT down counter will start counting from 0x3F to 0. To prevent program runs to disable WWDT counter counting unexpected, the WWDT control register WWDTCR can only be written once after chip is powered on or reset. User cannot disable WWDT counter counting (WWDTEN), change counter prescale period (PERIODSEL) or change window compare value (WINCMP) while WWDTEN bit has been enabled by software unless chip is reset.

WWDT Compare Match Interrupt

During down counting by the WWDT counter, the WWDTIF is set to 1 while the WWDT counter value (WWDTCVAL) is equal to WINCMP value and WWDTIF can be cleared by software; if WWDTIE is also set to 1 by software, the WWDT compare match interrupt signal is generated also while WWDTIF is set to 1 by hardware.

WWDT Reset System

When WWDTIF is generated, user must reload WWDT internal counter value to 0x3F by writing 0x00005AA5 to WWDTRLD, and also to prevent WWDT counter value reached to 0 and generate WWDT reset system signal to info system reset. If current WWDTCVAL value is larger than WINCMP value and user writes 0x00005AA5 to the WWDTRLD register, the WWDT reset system signal will be generated immediately to cause chip reset also.

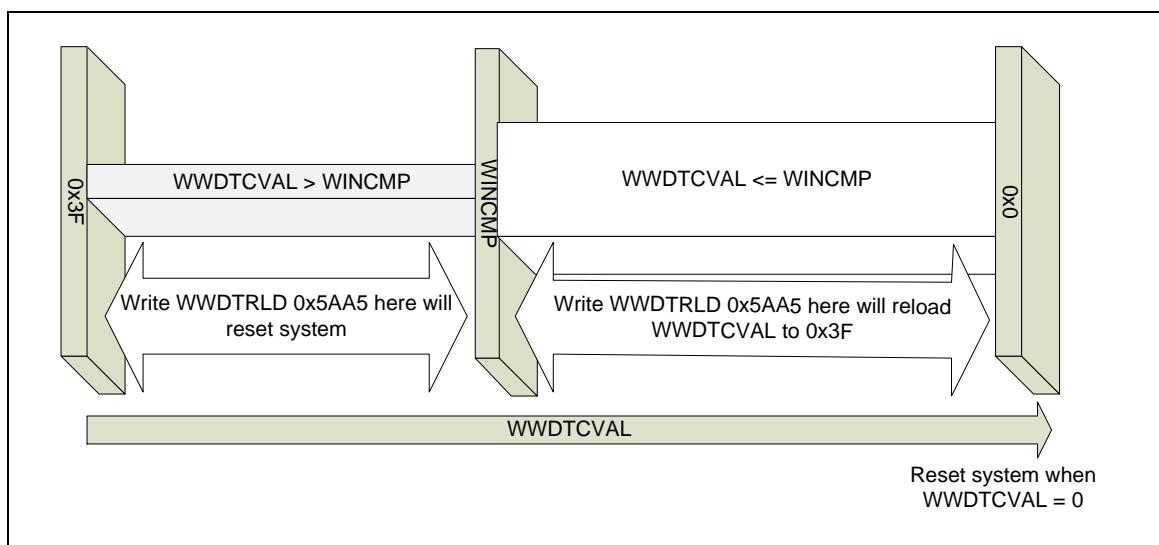

Figure 6-59 Window Watchdog Timer Reset and Reload Behavior

WWDT Window Setting Limitation

When user writes 0x00005AA5 to WWDTRLD to reload WWDT counter value to 0x3F, it needs 3 WWDT clocks to sync the reload command to actually perform reload action. This means if user set PERIODSEL to 0000, the counter prescale value should be as 1, and the WINCMP value must be larger than 2; otherwise, writing WWDTRLD to reload WWDT counter value to 0x3F is unavailable while WWDTIF is generated and WWDT reset system event always happened.

PERIODSEL	Prescale Value	Valid WINCMP Value
0000	1	0x3 ~ 0x3F
0001	2	0x2 ~ 0x3F
Others	Others	0x0 ~ 0x3F

Table 6-9 WINCMP Setting Limitation

6.11 UART Controller (UART)

6.11.1 Overview

The NuMicro® M05xxBN/DN/DE provides two channels of Universal Asynchronous Receiver/Transmitters (UART). UART Controller performs Normal Speed UART, and support flow control function. The UART Controller performs a serial-to-parallel conversion on data received from the peripheral, and a parallel-to-serial conversion on data transmitted from the CPU. The UART controller also supports IrDA SIR Function, LIN master/slave function and RS-485 function mode. Each UART Controller channel supports seven types of interrupts.

6.11.2 Features

- Full-duplex, asynchronous communications
- Separate receive / transmit 16/16 bytes entry FIFO for data payloads
- Supports hardware auto-flow control and flow control function (CTS, RTS) and programmable RTS flow control trigger level
- Programmable receiver buffer trigger level
- Supports programmable baud-rate generator for each channel individually
- Supports CTS wake-up function
- Supports 8-bit receiver buffer time-out detection function
- Programmable transmitting data delay time between the last stop and the next start bit by setting DLY (UA_TOR [15:8]) register
- Supports break error, frame error, parity error and receive / transmit buffer overflow detect function
- Fully programmable serial-interface characteristics
 - Programmable number of data bit, 5-, 6-, 7-, 8- bit character
 - Programmable parity bit, even, odd, no parity or stick parity bit generation and detection
 - Programmable stop bit, 1, 1.5, or 2 stop bit generation
- Supports IrDA SIR function mode
 - Supports for 3/16 bit duration for normal mode
- Supports LIN function mode
 - Supports LIN master/slave mode
 - Supports programmable break generation function for transmitter
 - Supports break detect function for receiver
- Supports RS-485 function mode
 - Supports RS-485 9-bit mode
 - Supports hardware or software enable to program RTS pin to control RS-485 transmission direction directly

6.11.3 Block Diagram

The UART clock control and block diagram are shown below.

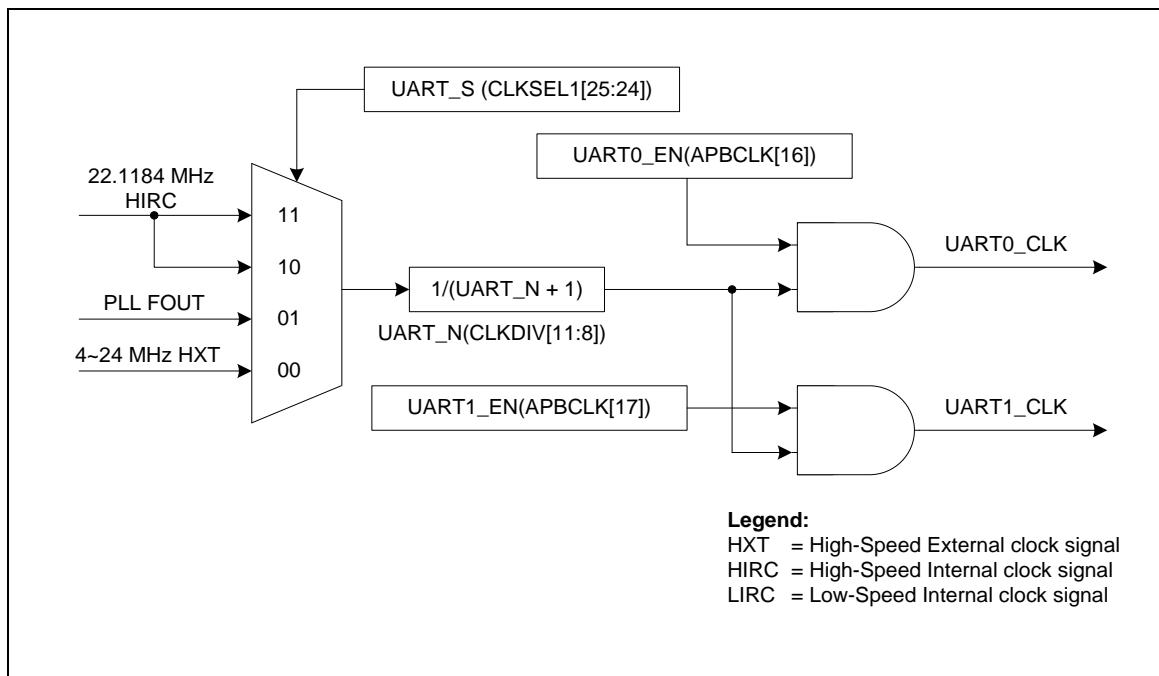

Figure 6-60 UART Controller Clock Control

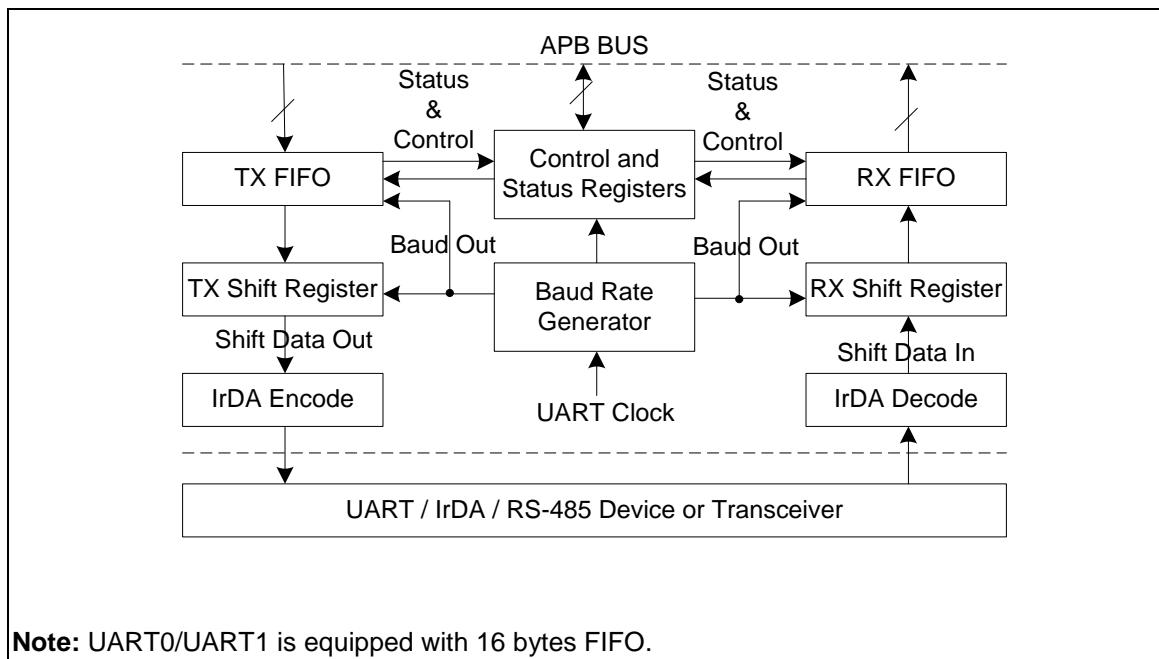

Figure 6-61 UART Controller Block Diagram

Each block is described in detail as follows:

TX_FIFO

The transmitter is buffered with a 16 bytes FIFO to reduce the number of interrupts presented to the CPU.

RX_FIFO

The receiver is buffered with a 16 bytes FIFO (plus three error bits per byte) to reduce the number of interrupts presented to the CPU.

TX Shift Register

This block is the shifting the transmitting data out serially control block.

RX Shift Register

This block is the shifting the receiving data in serially control block.

Modem Control Register

This register controls the interface to the MODEM or data set (or a peripheral device emulating a MODEM).

Baud Rate Generator

Divide the external clock by the divisor to get the desired baud rate clock. Refer to baud rate equation.

IrDA Encode

This block is IrDA encode control block.

IrDA Decode

This block is IrDA decode control block.

Control and Status Register

This field is register set that including the FIFO control registers (UA_FCR), FIFO status registers (UA_FSR), and line control register (UA_LCR) for transmitter and receiver. The time-out control register (UA_TOR) identifies the condition of time-out interrupt. This register set also includes the interrupt enable register (UA_IER) and interrupt status register (UA_ISR) to enable or disable the responding interrupt and to identify the occurrence of the responding interrupt. There are seven types of interrupts, transmitter FIFO empty interrupt(THRE_INT), receiver threshold level reaching interrupt (RDA_INT), line status interrupt (parity error or framing error or break interrupt) (RLS_INT), time-out interrupt (TOUT_INT), MODEM/Wake-up status interrupt (MODEM_INT), Buffer error interrupt (BUF_ERR_INT) and LIN receiver break field detected interrupt (LIN_RX_BREAK_INT).

In addition, the block diagram of auto-flow control is demonstrated in the following diagram.

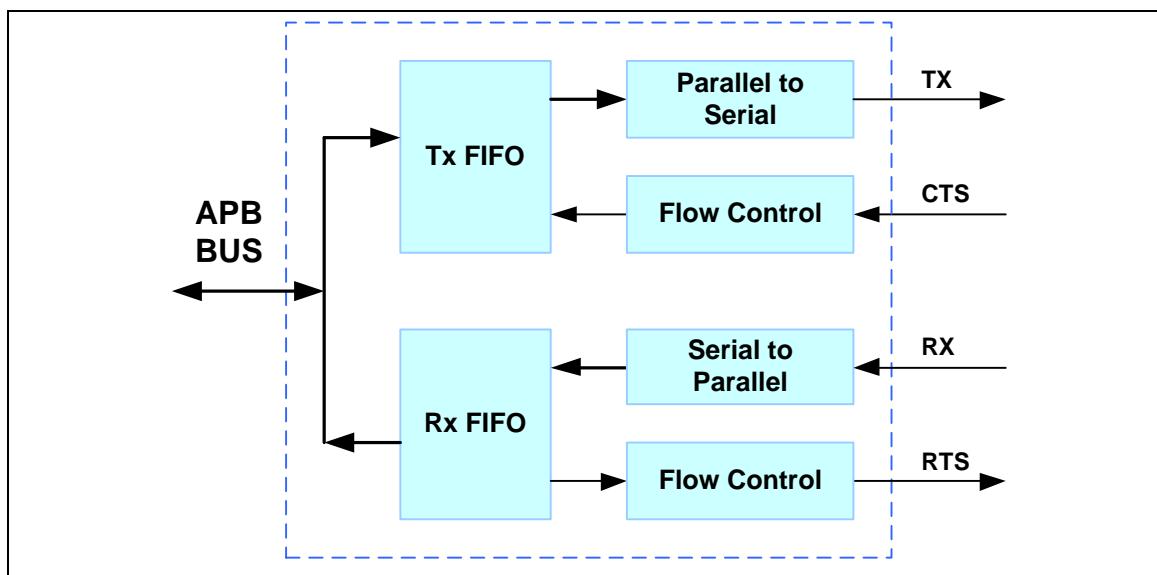

Figure 6-62 Auto Flow Control Block Diagram

6.11.4 Basic Configuration

The UART Controller function pins are configured in P0_MFP registers for UART0 and P3_MFP registers for UART1.

The UART Controller clock are enabled in UART0_EN(APBCLK[16]) for UART0 and UART1_EN(APBCLK[17]) for UART1.

The UART Controller clock source is selected by UART_S(CLKSEL[25:24]).

The UART Controller clock prescaler is determined by UART_N(CLKDIV[11:8]).

6.11.5 Functional Description

The UART Controller supports four function modes including UART, IrDA, LIN and RS-485 mode. User can select a function by setting the UA_FUN_SEL register. The four function modes will be described in detail in sections 6.10.5.1 to section 6.10.5.4. Also refer to sections 6.10.5.5 to section 1.1.5.8 for more information.

6.11.5.1 UART Controller Baud Rate Generator

The UART Controller includes a programmable baud rate generator capable of dividing clock input by divisors to produce the serial clock that transmitter and receiver need. The baud rate equation is $\text{Baud Rate} = \text{UART_CLK} / M * [\text{BRD} + 2]$, where M and BRD are defined in Baud Rate Divider Register (UA_BAUD). The following tables list the UART baud rate equations in the various conditions and UART baud rate parameter settings. There is no error for the baud rate results calculated through the baud rate parameter and register setting below. In IrDA function mode, the baud rate generator must be set in Mode 0.

Mode	DIV_X_EN	DIV_X_ONE	Divider X	BRD	M	Baud Rate Equation
Mode 0	0	0	B	A	16	UART_CLK / [16 * (A+2)]
Mode 1	1	0	B	A	B+1	UART_CLK / [(B+1) * (A+2)], B must >= 8
Mode 2	1	1	Don't care	A	1	UART_CLK / (A+2), A must >=8

Table 6-15 UART Controller Baud Rate Register Setting Table

6.11.5.2 UART Controller FIFO Control and Status

The UART Controller is built-in with a 16 bytes transmitter FIFO (TX_FIFO) and a 16 bytes receiver FIFO (RX_FIFO) that reduces the number of interrupts presented to the CPU. The CPU can read the status of the UART at any time during operation. The reported status information includes the type and condition of the transfer operations being performed by the UART, as well as 3 error conditions (parity error, framing error, break interrupt) probably occur while receiving data. This FIFO control and status also support all of UART, IrDA, LIN and RS-485 function mode.

6.11.5.3 UART Controller Wake-up Function

When the chip is in Power-down mode, an external CTS change will wake-up chip from Power-down mode. This wake-up function is available in every function mode. User must enable the MODEN_INT interrupt to use the wake-up function.

6.11.5.4 UART Controller Interrupt and Status

Each UART Controller supports seven types of interrupts including:

- Receiver threshold level reached interrupt (RDA_INT)
- Transmitter FIFO empty interrupt (THRE_INT)
- Line status interrupt (parity error, frame error or break interrupt) (RLS_INT)
- MODEM/Wake-up status interrupt (MODEM_INT)
- Receiver buffer time-out interrupt (TOUT_INT)
- Buffer error interrupt (BUF_ERR_INT)
- LIN receiver break field detected interrupt (LIN_RX_BREAK_INT)

The following tables describe the interrupt sources and flags for M05xxBN/DN/DE. The interrupt is generated when the interrupt flag is generated and the interrupt enable bit is set. User must clear the interrupt flag after the interrupt is generated.

Interrupt Source	Interrupt Indicator	Interrupt Enable Bit	Interrupt Flag	Flag Cleared By
Receive Data Available Interrupt	RDA_INT	RDA_IEN	RDA_IF	Read UA_RBR
Transmit Holding Register Empty Interrupt	THRE_INT	THRE_IEN	THRE_IF	Write UA_THR
Receive Line Status Interrupt	RLS_INT	RLS_IEN	RLS_IF = (BIF or FEF or PEF)	Writing '1' to RFR
			RLS_IF = RS485_ADD_DETF	Writing '1' to RS485_ADD_DETF
Modem Status Interrupt	MODEM_INT	MODEM_IEN	MODEM_IF = DCTS	Write '1' to DCTS
RX Time-out Interrupt	TOUT_INT	RTO_IEN	TOUT_IF	Read UA_RBR
Buffer Error Interrupt	BUF_ERR_INT	BUF_ERR_IEN	BUF_ERR_IF = (TX_OVER_IF or RX_OVER_IF)	Writing '1' to TX_OVER_IF / RX_OVER_IF
			BUF_ERR_IF = (BIF or FEF or PEF) (M05xxBN Only)	Writing '1' to RFR
LIN RX Break Field Detected interrupt	LIN_RX_BREAK_INT	LIN_RX_BRK_IEN	LIN_RX_BREAK_IF	Write '1' to LIN_RX_BREAK_IF

Table 6-16 UART Controller Interrupt Source and Flag List for M05xxBN

Interrupt Source	Interrupt Indicator	Interrupt Enable Bit	Interrupt Flag	Flag Cleared By
Receive Data Available Interrupt	RDA_INT	RDA_IEN	RDA_IF	Read UA_RBR
Transmit Holding Register Empty Interrupt	THRE_INT	THRE_IEN	THRE_IF	Write UA_THR
Receive Line Status Interrupt	RLS_INT	RLS_IEN	RLS_IF = (BIF or FEF or PEF)	Writing '1' to BIF/FEF/ PEF (M05xxDN/DE Only)
			RLS_IF = RS485_ADD_DETF	Writing '1' to RS485_ADD_DETF
Modem Status Interrupt	MODEM_INT	MODEM_IEN	MODEM_IF = DCTSF	Write '1' to DCTSF
RX Time-out Interrupt	TOUT_INT	RTO_IEN	TOUT_IF	Read UA_RBR
Buffer Error Interrupt	BUF_ERR_INT	BUF_ERR_IEN	BUF_ERR_IF = (TX_OVER_IF or RX_OVER_IF)	Writing '1' to TX_OVER_IF / RX_OVER_IF
LIN RX Break Field Detected interrupt	LIN_RX_BREAK_INT	LIN_RX_BRK_IEN	LIN_RX_BREAK_IF	Write '1' to LIN_RX_BREAK_IF

Table 6-17 UART Controller Interrupt Source and Flag List for M05xxDN/DE

6.11.5.5 UART Function Mode

The UART Controller provides UART function (user must set UA_FUN_SEL [1:0] to '00' to enable UART function mode). The UART baud rate is up to 1 Mbps.

The UART provides full-duplex and asynchronous communications. The transmitter and receiver contain 16 bytes FIFO for payloads. User can program receiver buffer trigger level and receiver buffer time-out detection for receiver. The transmitting data delay time between the last stop and the next start bit can be programmed by setting DLY (UA_TOR [15:8]) register. The UART supports hardware auto-flow control and flow control function (CTS, RTS), programmable RTS flow control trigger level and fully programmable serial-interface characteristics.

UART Line Control Function

The UART Controller supports fully programmable serial-interface characteristics by setting the UA_LCR register. Software can use the UA_LCR register to program the word length, stop bit and parity bit. The following tables list the UART word and stop bit length settings and the UART parity bit settings.

NSB (UA_LCR[2])	WLS (UA_LCR[1:0])	Word Length (Bit)	Stop Length (Bit)
0	00	5	1
0	01	6	1
0	10	7	1
0	11	8	1
1	00	5	1.5
1	01	6	2
1	10	7	2
1	11	8	2

Table 6-18 UART Line Control of Word and Stop Length Setting

Parity Type	SPE (UA_LCR[5])	EPE (UA_LCR[4])	PBE (UA_LCR[3])	Description
No Parity	x	x	0	No parity bit output.
Odd Parity	0	0	1	Odd Parity is calculated by adding all the "1's" in a data stream and adding a parity bit to the total bits, to make the total count an odd number.
Even Parity	0	1	1	Even Parity is calculated by adding all the "1's" in a data stream and adding a parity bit to the total bits, to make the count an even number.
Forced Mask Parity	1	0	1	Parity bit always logic 1. Parity bit on the serial byte is set to "1" regardless of total number of "1's" (even or odd counts).
Forced Space Parity	1	1	1	Parity bit always logic 0. Parity bit on the serial byte is set to "0" regardless of total number of "1's" (even or odd counts).

Table 6-19 UART Line Control of Parity Bit Setting

UART Auto-Flow Control Function

The UART supports auto-flow control function that uses two signals, CTS (clear-to-send) and RTS (request-to-send), to control the flow of data transfer between the UART and external devices (e.g. Modem). When auto flow is enabled, the UART is not allowed to receive data until the UART asserts RTS to external device. When the number of bytes in the RX FIFO equals the value of RTS_TRI_LEVEL (UA_FCR [19:16]), the RTS is de-asserted. The UART sends data out when UART detects CTS is asserted from external device. If the valid asserted CTS is not detected, the UART will not send data out.

The following diagram demonstrates the CTS auto flow control of UART function mode. User must set AUTO_CTS_EN (UA_IER [13]) to enable CTS auto flow control function. The LEV_CTS (UA_MCR [8]) can set CTS pin input active state. The DCTS (UA_MSR [0]) is set when any state change of CTS pin input has occurred, and then TX data will be automatically transmitted from TX FIFO.

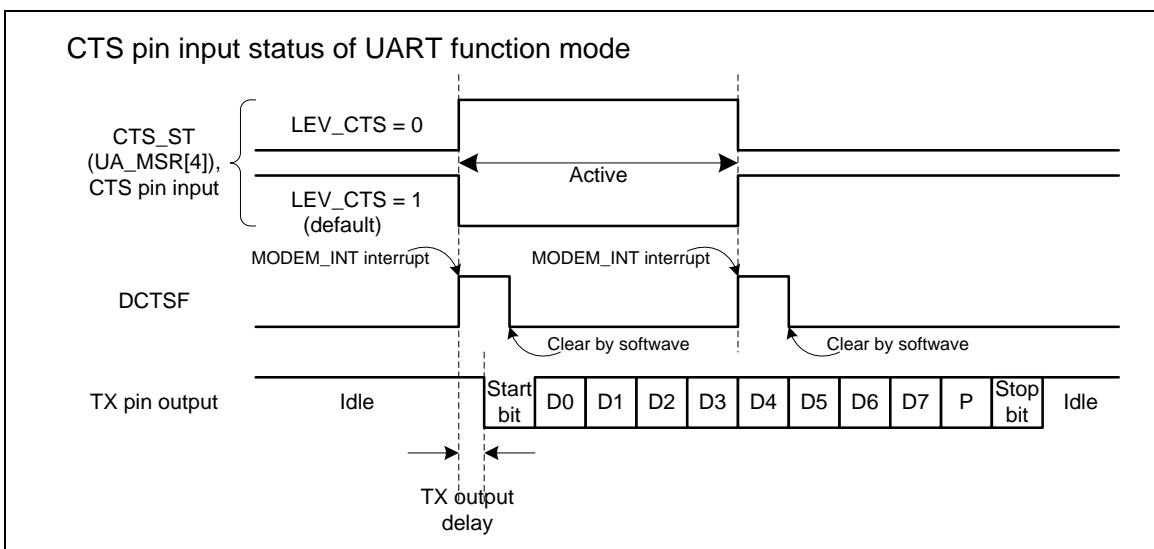

Figure 6-63 UART CTS Auto Flow Control Enabled

As shown in the following figure, in UART RTS Auto Flow control mode (AUTO_RTS_EN(UA_IER[12])=1), the nRTS internal signal is controlled by UART FIFO controller with RTS_RTI_lev(UA_FCR[19:16]) trigger level.

Setting LEV_RTS(UA_MCR[9]) can control the RTS pin output is inverse or non-inverse from nRTS signal. User can read the RTS_ST(UA_MCR[13]) bit to get real RTS pin output voltage logic status.

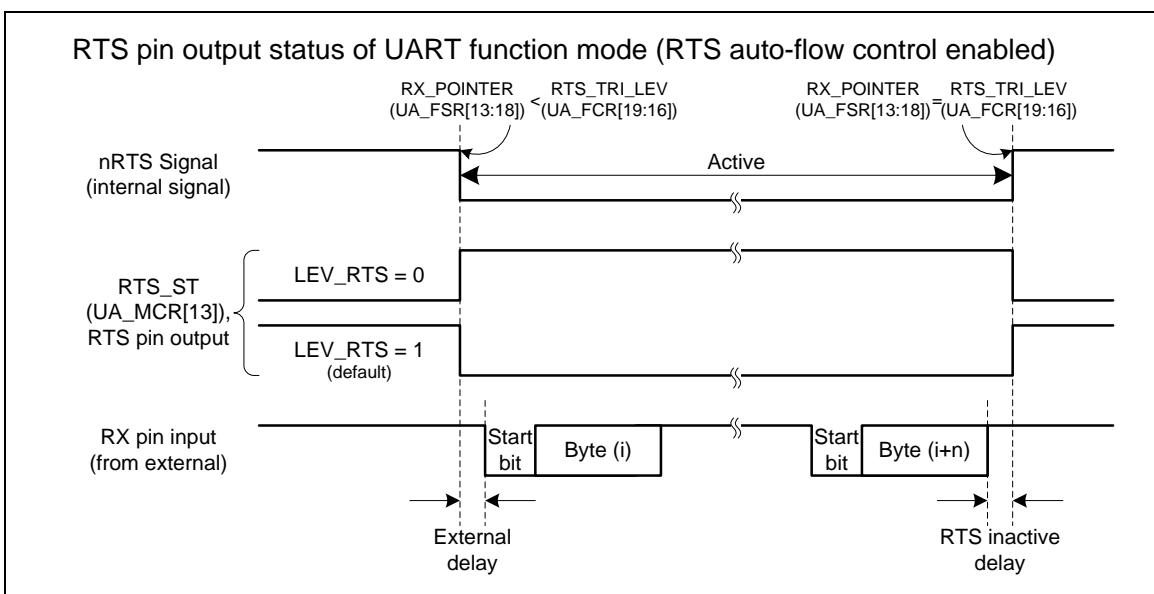

Figure 6-64 UART RTS Auto Flow Control Enabled

As shown in the following figure, in software mode (AUTO_RTS_EN(UA_IER[12])=0) the RTS flow is directly controlled by software programming of RTS(UA_MCR[1]) control bit.

Setting LEV_RTS(UA_MCR[9]) can control the RTS pin output is inverse or non-inverse from RTS(UA_MCR[1]) control bit. User can read the RTS_ST(UA_MCR[13]) bit to get real RTS pin output voltage logic status.

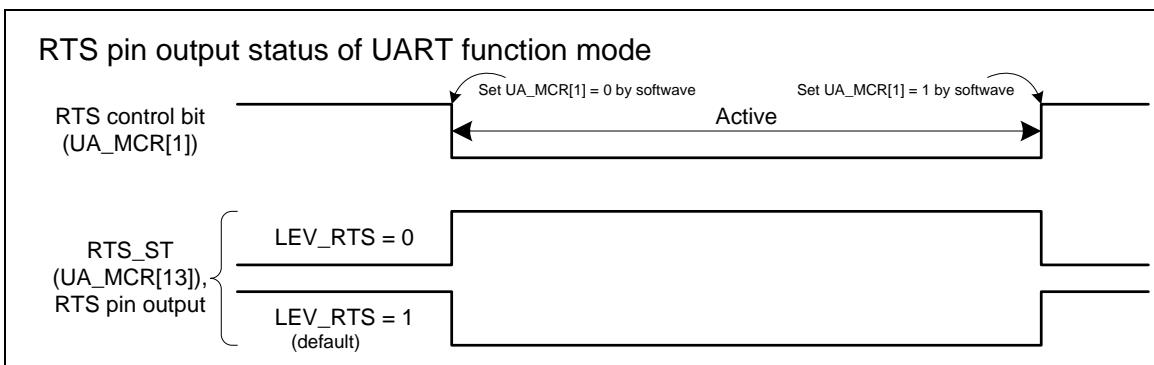

Figure 6-65 UART RTS Flow with Software Control

6.11.5.6 IrDA Function Mode

The UART Controller also provides Serial IrDA (SIR, Serial Infrared) function (user must set UA_FUN_SEL [1:0] to '10' to enable the IrDA function). The SIR specification defines a short-range infrared asynchronous serial transmission mode with one start bit, 8 data bits, and 1 stop bit. The maximum data rate is 115.2 kbps. The IrDA SIR block contains an IrDA SIR protocol encoder/decoder. The IrDA SIR protocol is half-duplex only. So it cannot transmit and receive data at the same time. The IrDA SIR physical layer specifies a minimum 10 ms transfer delay between transmission and reception, and this delay feature must be implemented by software.

In IrDA mode, the DIV_X_EN (UA_BAUD [29]) register must be disabled.

Baud Rate = Clock / (16 * BRD), where BRD is Baud Rate Divider in UA_BAUD register.

The following diagram demonstrates the IrDA control block diagram.

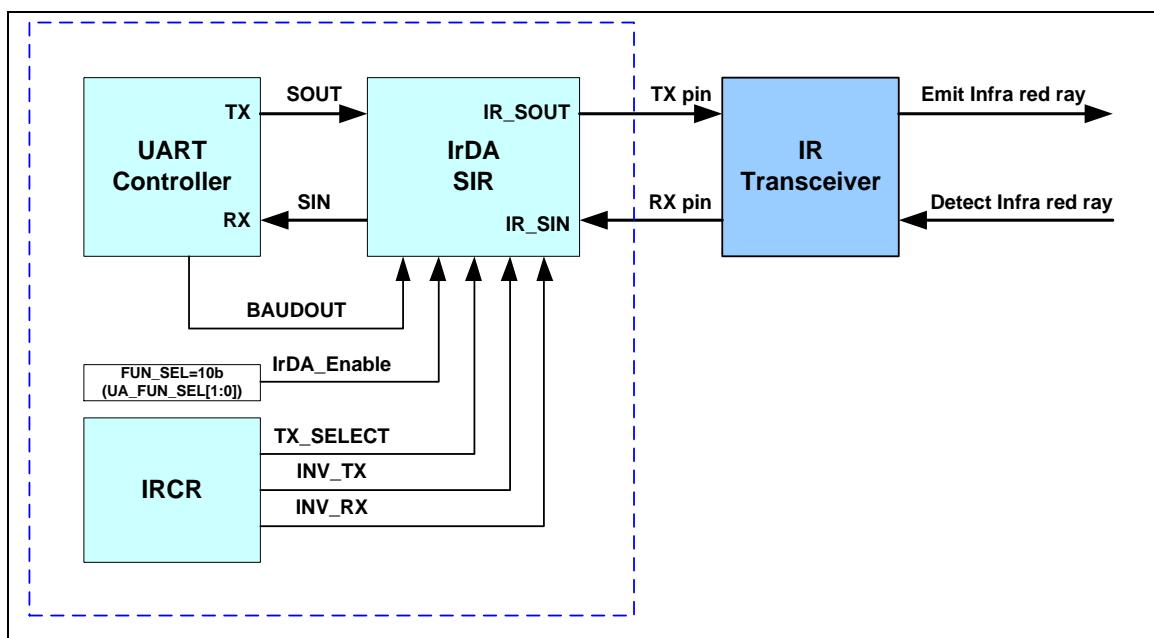

Figure 6-66 IrDA Control Block Diagram

IrDA SIR Transmit Encoder

The IrDA SIR Transmit Encoder modulates Non-Return-to Zero (NRZ) transmit bit stream output from UART. The IrDA SIR physical layer specifies the use of Return-to-Zero, Inverted (RZI) modulation scheme which represents logic 0 as an infra light pulse. The modulated output pulse stream is transmitted to an external output driver and infrared light emitting diode.

In Normal mode, the transmitted pulse width is specified as 3/16 period of baud rate.

IrDA SIR Receive Decoder

The IrDA SIR Receive Decoder demodulates the Return-to-Zero bit stream from the input detector and outputs the NRZ serial bits stream to the UART received data input. The decoder input is normally high in idle state. (Because of this, IRCR (INV_RX [6]) should be set as 1 by default).

A start bit is detected when the decoder input is LOW.

IrDA SIR Operation

The IrDA SIR encoder/decoder provides functionality which converts between UART data stream and half-duplex serial SIR interface. The following diagram is IrDA encoder/decoder waveform.

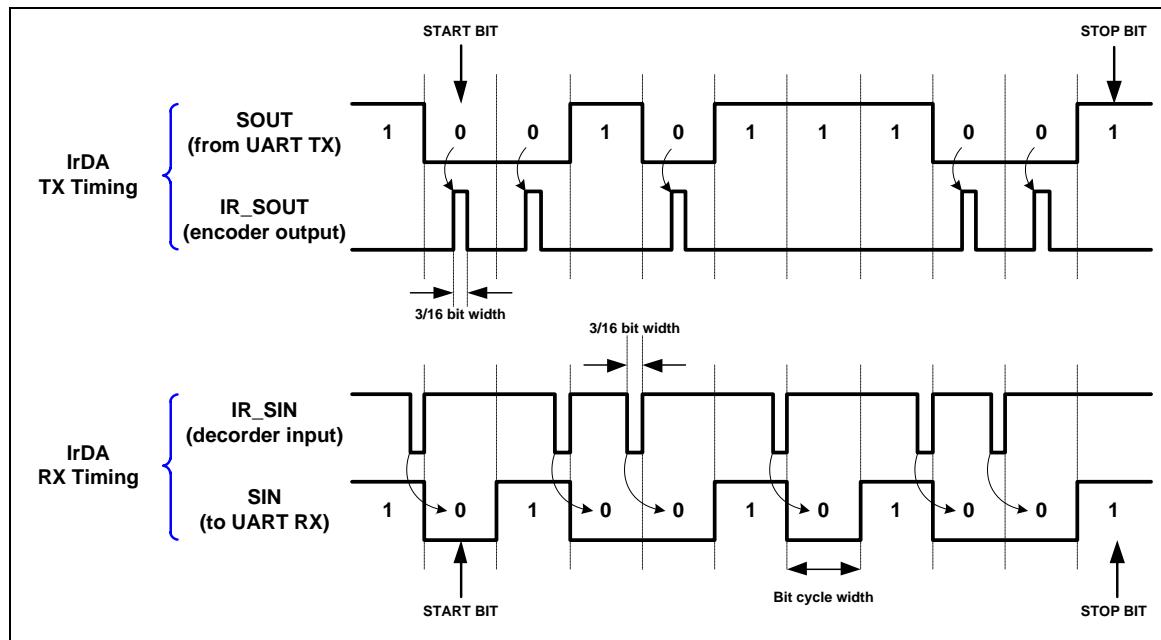

Figure 6-67 IrDA TX/RX Timing Diagram

6.11.5.7 LIN (Local Interconnection Network) Function Mode

The UART Controller supports LIN function (user must set UA_FUN_SEL [1:0] to '01' to enable LIN function). In LIN function mode, each byte field is initiated by a start bit with value 0 (dominant), followed by 8 data bits (LSB is first) and ended by 1 stop bit with value one (recessive) in accordance with the LIN standard. The following diagram is the structure of LIN function mode:

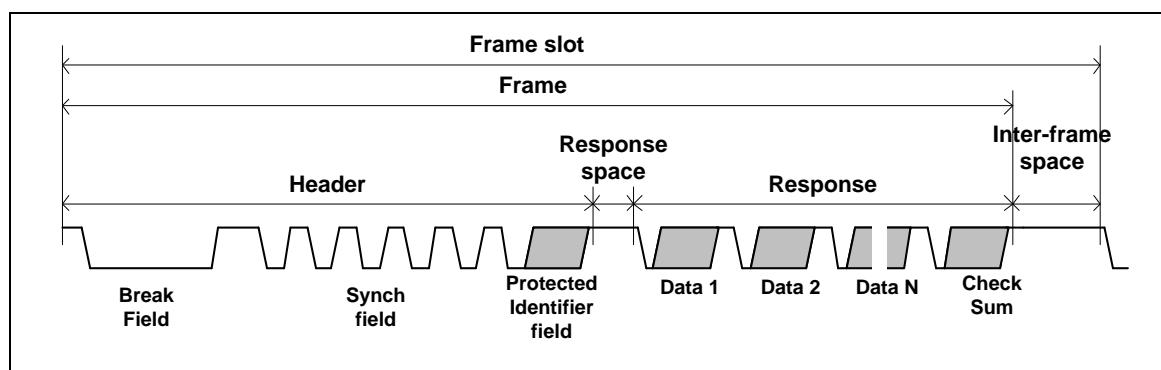

Figure 6-68 Structure of LIN Frame

The program flow of LIN bus transmit transfer (TX) is shown as follows:

1. Setting the UA_FUN_SEL[1:0] to '01' to enable LIN bus mode.
2. Fill UA_LIN_BKFL in UA_LIN_BCNT to choose break field length. (The break field length is UA_LIN_BKFL + 2).
3. Fill 0x55 to UA_THR to request synch field transmission.
4. Request identifier field transmission by writing the protected identifier value in the UA_THR
5. Setting the LIN_TX_EN bit in UA_LIN_BCNT register to start transmission. (When break filed operation is finished, LIN_TX_EN will be cleared automatically).
6. When the STOP bit of the last byte THR has been sent to bus, hardware will set flag TE_FLAG in UA_FSR to 1.
7. Fill N bytes data and checksum to UA_THR then repeat step 5 and 6 to transmit the data.

The program flow of LIN bus receiver transfer (RX) is show as follows:

1. Setting the UA_FUN_SEL[1:0] to '01' to enable LIN bus mode.
2. Setting the LIN_RX_EN bit in UA_LIN_BCNT register to enable LIN RX mode.
3. Waiting for the flag LIN_RX_BREAK_IF in UA_ISR to check RX received break field or not.
4. Waiting for the flag RDA_IF in UA_ISR and read back the UR_RBR register.

6.11.5.8 RS-485 Function Mode

Another alternate function of UART Controller is RS-485 function (user must set UA_FUN_SEL [1:0] to '11' to enable RS-485 function), and direction control provided by RTS pin or can program GPIO (P0.3 for RTS0 and P0.1 for RTS1) to implement the function by software. The RS-485 transceiver control is implemented by using the RTS control signal from an asynchronous serial port to enable the RS-485 driver. Many characteristics of the RX and TX are same as UART in RS-485 mode

The controller can configuration of it as an RS-485 addressable slave and the RS-485 master transmitter will identify an address character by setting the parity (9-th bit) to 1. For data characters, the parity is set to 0. Software can use UA_LCR register to control the 9-th bit (When the PBE, EPE and SPE are set, the 9-th bit is transmitted 0 and when PBE and SPE are set and EPE is cleared, the 9-th bit is transmitted 1).

The controller supports three operation modes: RS-485 Normal Multidrop Operation Mode (NMM), RS-485 Auto Address Detection Operation Mode (AAD) and RS-485 Auto Direction Control Operation Mode (AUD). Software can choose any operation mode by programming the UA_ALT_CSR register, and drive the transfer delay time between the last stop bit leaving the TX FIFO and the de-assertion of by setting DLY (UA_TOR [15:8]) register.

RS-485 Normal Multidrop Operation Mode (NMM)

In RS-485 Normal Multidrop Operation Mode, in first, software must decide the data which before the address byte be detected will be stored in RX FIFO or not. If software wants to ignore any data before address byte detected, the flow is set RX_DIS (UA_FCR [8]) then enable RS485_NMM (UA_ALT_CSR [8]) and the receiver will ignore any data until an address byte is detected (bit 9 = 1) and the address byte data will be stored in the RX FIFO. If software wants to receive any data before address byte detected, the flow is disables RX_DIS (UA_FCR [8]) then

enable RS485_NMM (UA_ALT_CSR [8]) and the receiver will received any data.

If an address byte is detected (bit 9 = 1), it will generate an interrupt to CPU and RX_DIS (UA_FCR [8]) can decide whether accepting the following data bytes are stored in the RX FIFO. If software disables receiver by setting RX_DIS (UA_FCR [8]) register, when a next address byte is detected, the controller will clear the RX_DIS (UA_FCR [8]) bit and the address byte data will be stored in the RX FIFO.

RS-485 Auto Address Detection Operation Mode (AAD)

In RS-485 Auto Address Detection Operation Mode, the receiver will ignore any data until an address byte is detected (bit 9 = 1) and the address byte data matches the ADDR_MATCH (UA_ALT_CSR[31:24]) value. The address byte data will be stored in the RX FIFO. The all received byte data will be accepted and stored in the RX FIFO until and address byte data not match the ADDR_MATCH (UA_ALT_CSR[31:24]) value.

RS-485 Auto Direction Mode (AUD)

Another option function of RS-485 controllers is **RS-485 auto direction control function**. User must set RS485_AUD(UA_ALT_CSR[10]) to 1 to enabled RS-485 auto direction mode. The RS-485 transceiver control is implemented using the RTS control signal from an asynchronous serial port. The RTS line is connected to the RS-485 transceiver enable pin such that setting the RTS line to high (logic 1) enables the RS-485 transceiver. Setting the RTS line to low (logic 0) puts the transceiver into the tri-state condition to disabled. User can set LEV_RTS in UA_MCR register to change the RTS driving level.

The following diagram demonstrates the RS-485 RTS driving level in AUD mode. The RTS pin will be automatically driven during TX data transmission.

Setting LEV_RTS(UA_MCR[9]) can control RTS pin output driving level. User can read the RTS_ST(UA_MCR[13]) bit to get real RTS pin output voltage logic status.

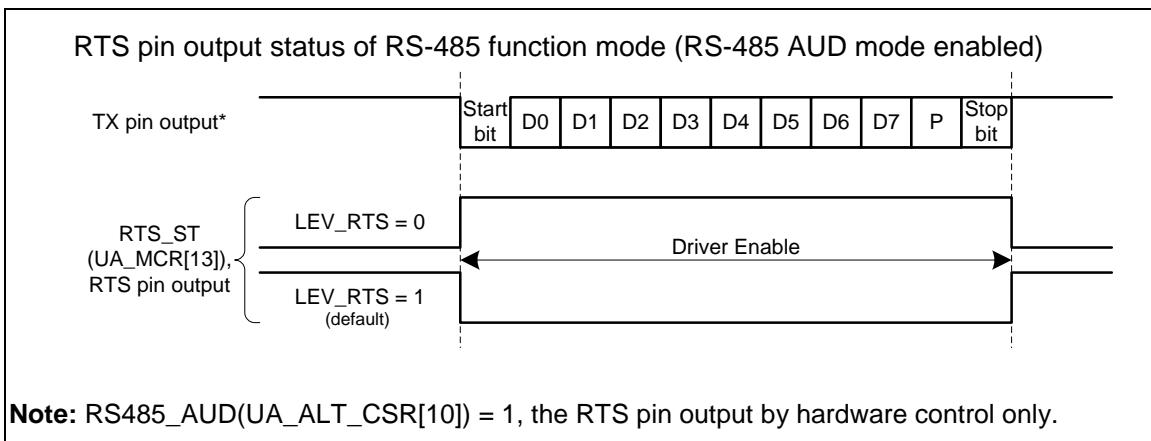

Figure 6-69 RS-485 RTS Driving Level in Auto Direction Mode

The following diagram demonstrates the RS-485 RTS driving level in software control (RS485_AUD(UA_ALT_CSR[10])=0). The RTS driving level is controlled by programming the RTS(UA_MCR[1]) control bit.

Setting LEV_RTS(UA_MCR[9]) can control the RTS pin output is inverse or non-inverse from RTS(UA_MCR[1]) control bit. User can read the RTS_ST(UA_MCR[13]) bit to get real RTS pin output voltage logic status.

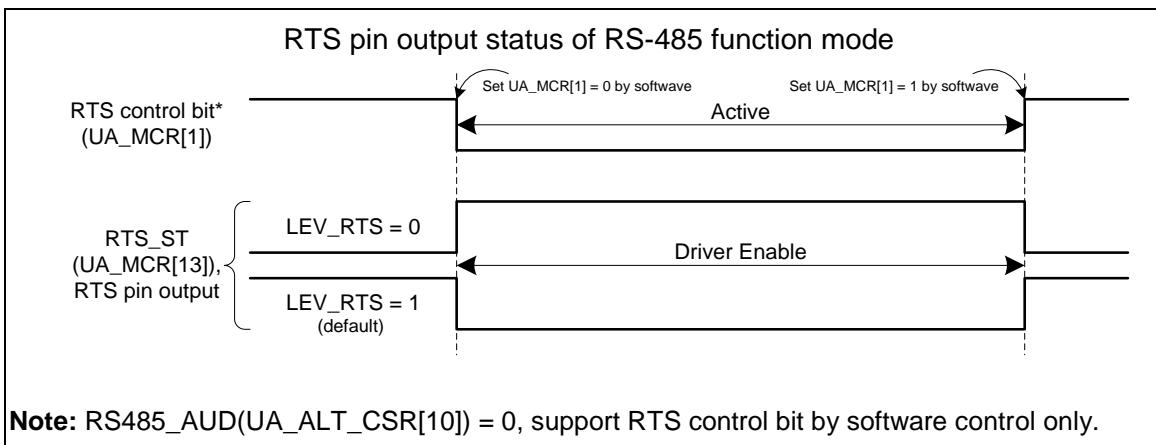

Figure 6-70 RS-485 RTS Driving Level with Software Control

Program Sequence Example:

1. Program FUN_SEL in UA_FUN_SEL to select RS-485 function.
2. Program the RX_DIS bit in UA_FCR register to determine enable or disable the receiver RS-485 receiver
3. Program the RS485_NMM or RS485_AAD mode.
4. If the RS485_AAD mode is selected, the ADDR_MATCH is programmed for auto address match value.
5. Determine auto direction control by programming RS485_AUD.

RX_FULL	RX_EMPTY	RX_POINTER					
7	6	5	4	3	2	1	0
Reserved	BIF	FEF	PEF	RS485_ADD_DET	Reserved		RX_OVER_IF

Bits	Description	
[31:29]	Reserved	Reserved.
[28]	TE_FLAG	<p>Transmitter Empty Flag (Read Only) This bit is set by hardware when TX FIFO (UA_THR) is empty and the STOP bit of the last byte has been transmitted. 0 = TX FIFO is not empty. 1 = TX FIFO is empty. Note: This bit is cleared automatically when TX FIFO is not empty or the last byte transmission has not completed.</p>
[27:25]	Reserved	Reserved.
[24]	TX_OVER_IF	<p>TX Overflow Error Interrupt Flag If TX FIFO (UA_THR) is full, an additional write to UA_THR will cause this bit to logic 1. 0 = TX FIFO is not overflow. 1 = TX FIFO is overflow. Note: This bit is cleared by writing 1 to it.</p>
[23]	TX_FULL	<p>Transmitter FIFO Full (Read Only) This bit indicates TX FIFO full or not. 0 = TX FIFO is not full. 1 = TX FIFO is full. Note: This bit is set when the number of usage in TX FIFO Buffer is equal to 16, otherwise is cleared by hardware.</p>
[22]	TX_EMPTY	<p>Transmitter FIFO Empty (Read Only) This bit indicates TX FIFO empty or not. 0 = TX FIFO is not empty. 1 = TX FIFO is empty. Note: When the last byte of TX FIFO has been transferred to Transmitter Shift Register, hardware sets this bit high. It will be cleared when writing data into THR (TX FIFO not</p>

		empty).
[21:16]	TX_POINTER	<p>TX FIFO Pointer (Read Only)</p> <p>This field indicates the TX FIFO Buffer Pointer. When CPU writes one byte into UA_THR, TX_POINTER increases one. When one byte of TX FIFO is transferred to Transmitter Shift Register, TX_POINTER decreases one.</p> <p>The Maximum value shown in TX_POINTER is 15. When the using level of TX FIFO Buffer equal to 16, the TX_FULL bit is set to 1 and TX_POINTER will show 0. As one byte of TX FIFO is transferred to Transmitter Shift Register, the TX_FULL bit is cleared to 0 and TX_POINTER will show 15.</p>
[15]	RX_FULL	<p>Receiver FIFO Full (Read Only)</p> <p>This bit initiates RX FIFO full or not.</p> <p>0 = RX FIFO is not full. 1 = RX FIFO is full.</p> <p>Note: This bit is set when the number of usage in RX FIFO Buffer is equal to 16, otherwise is cleared by hardware.</p>
[14]	RX_EMPTY	<p>Receiver FIFO Empty (Read Only)</p> <p>This bit initiate RX FIFO empty or not.</p> <p>0 = RX FIFO is not empty. 1 = RX FIFO is empty.</p> <p>Note: When the last byte of RX FIFO has been read by CPU, hardware sets this bit high. It will be cleared when UART receives any new data.</p>
[13:8]	RX_POINTER	<p>RX FIFO Pointer (Read Only)</p> <p>This field indicates the RX FIFO Buffer Pointer. When UART receives one byte from external device, RX_POINTER increases one. When one byte of RX FIFO is read by CPU, RX_POINTER decreases one.</p> <p>The Maximum value shown in RX_POINTER is 15. When the using level of RX FIFO Buffer equal to 16, the RX_FULL bit is set to 1 and RX_POINTER will show 0. As one byte of RX FIFO is read by CPU, the RX_FULL bit is cleared to 0 and RX_POINTER will show 15.</p>
[7]	Reserved	Reserved.
[6]	BIF	<p>Break Interrupt Flag (Read Only)</p> <p>This bit is set to logic 1 whenever the received data input (RX) is held in the “spacing state” (logic 0) for longer than a full word transmission time (that is, the total time of “start bit” + data bits + parity + stop bits).</p> <p>0 = No Break interrupt is generated. 1 = Break interrupt is generated.</p> <p>Note1: This bit is read only, but can be cleared by writing ‘1’ to it (M05xxDN/DE Only). Note2: This bit is read only, but can be cleared by writing ‘1’ to RFR (UA_FCR [1]) (Available on M05xxBN and M05xxDN/DE).</p>
[5]	FEF	<p>Framing Error Flag (Read Only)</p> <p>This bit is set to logic 1 whenever the received character does not have a valid “stop bit” (that is, the stop bit following the last data bit or parity bit is detected as logic 0).</p> <p>0 = No framing error is generated. 1 = Framing error is generated.</p> <p>Note1: This bit is read only, but can be cleared by writing ‘1’ to it (M05xxDN/DE Only). Note2: This bit is read only, but can be cleared by writing ‘1’ to RFR (UA_FCR [1]) (Available on M05xxBN and M05xxDN/DE).</p>
[4]	PEF	<p>Parity Error Flag (Read Only)</p> <p>This bit is set to logic 1 whenever the received character does not have a valid “parity bit”.</p> <p>0 = No parity error is generated.</p>

		<p>1 = Parity error is generated.</p> <p>Note1: This bit is read only, but can be cleared by writing '1' to it (M05xxDN/DE Only).</p> <p>Note2: This bit is read only, but can be cleared by writing '1' to RFR (UA_FCR [1]) (Available on M05xxBN and M05xxDN/DE).</p>
[3]	RS485_ADD_DETF	<p>RS-485 Address Byte Detection Flag</p> <p>This bit is set to 1 while RS485_ADD_EN (UA_ALT_CSR[15]) is set to 1 to enable Address detection mode and receive detect a data with an address bit (bit 9 = 1).</p> <p>Note1: This field is used for RS-485 function mode.</p> <p>Note2: This bit is cleared by writing 1 to it.</p>
[2:1]	Reserved	Reserved.
[0]	RX_OVER_IF	<p>RX Overflow Error Interrupt Flag</p> <p>This bit is set when RX FIFO overflow.</p> <p>If the number of bytes of received data is greater than RX_FIFO (UA_RBR) size, 16 bytes this bit will be set.</p> <p>0 = RX FIFO is not overflow. 1 = RX FIFO is overflow.</p> <p>Note: This bit is cleared by writing 1 to it.</p>

UART Interrupt Status Control Register (UA_ISR)

Register	Offset	R/W	Description				Reset Value
UA_ISR x=0,1	UARTx_BA+0x1C	R/W	UART Interrupt Status Register				0x0000_0002

Bits	Description	
[31:14]	Reserved	Reserved.
[15]	LIN_RX_BREAK_INT	LIN Bus RX Break Field Detected Interrupt Indicator (Read Only) This bit is set if LIN_RX_BRK_IEN and LIN_RX_BREAK_IF are both set to 1. 0 = No LIN RX Break interrupt is generated. 1 = LIN RX Break interrupt is generated.
[14]	Reserved	Reserved.
[13]	BUF_ERR_INT	Buffer Error Interrupt Indicator (Read Only) This bit is set if BUF_ERR_IEN and BUF_ERR_IF are both set to 1. 0 = No buffer error interrupt is generated. 1 = buffer error interrupt is generated.
[12]	TOUT_INT	Time-out Interrupt Indicator (Read Only) This bit is set if RTO_IEN and TOUT_IF are both set to 1. 0 = No Time-out interrupt is generated. 1 = Time-out interrupt is generated.
[11]	MODEM_INT	MODEM Status Interrupt Indicator (Read Only) This bit is set if MODEM_IEN and MODEM_IF are both set to 1. 0 = No Modem interrupt is generated. 1 = Modem interrupt is generated.
[10]	RLS_INT	Receive Line Status Interrupt Indicator (Read Only) This bit is set if RLS_IEN and RLS_IF are both set to 1. 0 = No RLS interrupt is generated. 1 = RLS interrupt is generated.
[9]	THRE_INT	Transmit Holding Register Empty Interrupt Indicator (Read Only) This bit is set if THRE_IEN and THRE_IF are both set to 1.

		0 = No THRE interrupt is generated. 1 = THRE interrupt is generated.
[8]	RDA_INT	<p>Receive Data Available Interrupt Indicator (Read Only)</p> <p>This bit is set if RDA_IEN and RDA_IF are both set to 1.</p> <p>0 = No RDA interrupt is generated. 1 = RDA interrupt is generated.</p>
[7]	LIN_RX_BREAK_IF	<p>LIN Bus RX Break Field Detected Flag</p> <p>This bit is set when RX received LIN Break Field. If LIN_RX_BRK_IEN (UA_IER [8]) is enabled the LIN RX Break interrupt will be generated.</p> <p>0 = No LIN RX Break received. 1 = LIN RX Break received.</p> <p>Note: This bit is cleared by writing 1 to it.</p>
[6]	Reserved	Reserved.
[5]	BUF_ERR_IF	<p>Buffer Error Interrupt Flag (Read Only)</p> <p>This bit is set when the TX/RX FIFO overflow flag (TX_OVER_IF or RX_OVER_IF) is set. On M05xxBN, this bit is also set when Break Interrupt Flag, Parity Error Flag or Frame Error Flag (BIF, PEF or FEF) is set.</p> <p>When BUF_ERR_IF is set, the transfer is not correct. If BUF_ERR_IEN (UA_IER [5]) is enabled, the buffer error interrupt will be generated.</p> <p>0 = No buffer error interrupt flag is generated. 1 = Buffer error interrupt flag is generated.</p> <p>Note1: On M05xxDN/DE, this bit is read only and reset to 0 when all bits of TX_OVER_IF and RX_OVER_IF are cleared. (M05xxDN/DE Only)</p> <p>Note2: On M05xxBN, this bit is read only and reset to 0 when all bits of TX_OVER_IF, RX_OVER_IF, BIF, FEF and PEF are cleared. (M05xxBN Only)</p>
[4]	TOUT_IF	<p>Time-out Interrupt Flag (Read Only)</p> <p>This bit is set when the RX FIFO is not empty and no activities occurred in the RX FIFO and the time-out counter equal to TOIC. If RTO_IEN (UA_IER [4]) is enabled, the Tout interrupt will be generated.</p> <p>0 = No Time-out interrupt flag is generated. 1 = Time-out interrupt flag is generated.</p> <p>Note: This bit is read only and user can read UA_RBR (RX is in active) to clear it.</p>
[3]	MODEM_IF	<p>MODEM Interrupt Flag (Read Only)</p> <p>This bit is set when the CTS pin has state change (DCTSF = 1). If UA_IER [MODEM_IEN] is enabled, the Modem interrupt will be generated.</p> <p>0 = No Modem interrupt flag is generated. 1 = Modem interrupt flag is generated.</p> <p>Note: This bit is read only and reset to 0 when bit DCTSF is cleared by a write 1 on DCTSF.</p>
[2]	RLS_IF	<p>Receive Line Interrupt Flag (Read Only)</p> <p>This bit is set when the RX receive data have parity error, framing error or break error (at least one of 3 bits, BIF, FEF and PEF, is set). If RLS_IEN (UA_IER [2]) is enabled, the RLS interrupt will be generated.</p> <p>0 = No RLS interrupt flag is generated. 1 = RLS interrupt flag is generated.</p> <p>Note1: In RS-485 function mode, this field is set including "receiver detect and received address byte character (bit 9 = 1) bit". At the same time, the bit of RS485_ADD_DETF (UA_FSR[3]) is also set.</p> <p>Note2: This bit is read only and reset to 0 when all bits of BIF, FEF, PEF and RS485_ADD_DETF are cleared.</p>

[1]	THRE_IF	Transmit Holding Register Empty Interrupt Flag (Read Only) This bit is set when the last data of TX FIFO is transferred to Transmitter Shift Register. If THRE_IEN (UA_IER [1]) is enabled, the THRE interrupt will be generated. 0 = No THRE interrupt flag is generated. 1 = THRE interrupt flag is generated. Note: This bit is read only and it will be cleared when writing data into THR (TX FIFO not empty).
[0]	RDA_IF	Receive Data Available Interrupt Flag (Read Only) When the number of bytes in the RX FIFO equals the RFITL then the RDA_IF will be set. If RDA_IEN (UA_IER [0]) is enabled, the RDA interrupt will be generated. 0 = No RDA interrupt flag is generated. 1 = RDA interrupt flag is generated. Note: This bit is read only and it will be cleared when the number of unread bytes of RX FIFO drops below the threshold level (RFITL).

UART Time-out Register (UA_TOR)

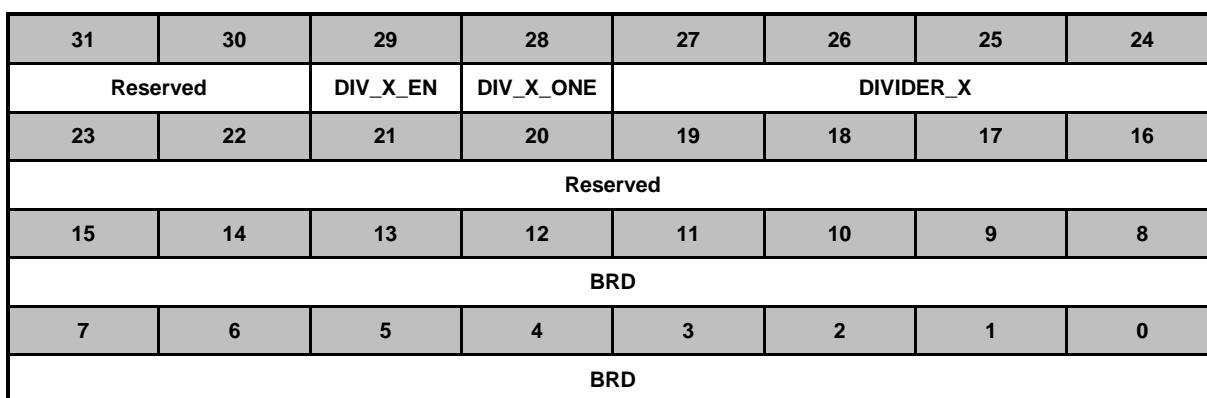

Register	Offset	R/W	Description	Reset Value
UA_TOR x=0,1	UARTx_BA+0x20	R/W	UART Time-out Register	0x0000_0000

Bits	Description	
[31:16]	Reserved	Reserved.
[15:8]	DLY	TX Delay Time Value This field is used to program the transfer delay time between the last stop bit and next start bit.  TX --- [Byte (i)] --- DLY --- [Byte (i+1)] --- <ul style="list-style-type: none"> Start Stop DLY Start
[7:0]	TOIC	Time-out Interrupt Comparator The time-out counter resets and starts counting (the counting clock = baud rate) whenever the RX FIFO receives a new data word. Once the content of time-out counter (TOUT_CNT) is equal to that of time-out interrupt comparator (TOIC), a receiver time-out interrupt (TOUT_INT) is generated if RTO_IEN (UA_IER [4]). A new incoming data word or RX FIFO empty clears TOUT_INT. In order to avoid receiver time-out interrupt generation immediately during one character is being received, TOIC value should be set between 40 and 255. So, for example, if TOIC is set with 40, the time-out interrupt is generated after four characters are not received when 1 stop bit and no parity check is set for UART transfer.

UART Baud Rate Divider Register (UA_BAUD)

Register	Offset	R/W	Description	Reset Value
UA_BAUD x=0,1	UARTx_BA+0x24	R/W	UART Baud Rate Divisor Register	0x0F00_0000

Bits	Description	
[31:30]	Reserved	Reserved.
[29]	DIV_X_EN	<p>Divider X Enable Control The BRD = Baud Rate Divider, and the baud rate equation is Baud Rate = Clock / [M * (BRD + 2)]; The default value of M is 16. 0 = Divider X Disabled (the equation of M = 16). 1 = Divider X Enabled (the equation of M = X+1, but DIVIDER_X[27:24] must >= 8). Note1: Refer to the section 6.11.5.1 for more information. Note2: In IrDA function mode, this bit must disable.</p>
[28]	DIV_X_ONE	<p>Divider X Equal 1 0 = Divider M = X (the equation of M = X+1, but DIVIDER_X[27:24] must >= 8). 1 = Divider M = 1 (the equation of M = 1, but BRD [15:0] must >= 8). Note1: Refer to the section 6.11.5.1 for more information.</p>
[27:24]	DIVIDER_X	<p>Divider X The baud rate divider M = X+1.</p>
[23:16]	Reserved	Reserved.
[15:0]	BRD	<p>Baud Rate Divider The field indicated the baud rate divider.</p>

6.12 I²C Serial Interface Controller (I²C)

6.12.1 Overview

I²C is a two-wire, bi-directional serial bus that provides a simple and efficient method of data exchange between devices. The I²C standard is a true multi-master bus including collision detection and arbitration that prevents data corruption if two or more masters attempt to control the bus simultaneously.

There are two sets of I²C which supports Power-down wake-up function in M05xxDN/DE series.

6.12.2 Features

The I²C bus uses two wires (SDA and SCL) to transfer information between devices connected to the bus. The main features of the I²C bus include:

- Supports up to two I²C ports
- Master/Slave mode
- Bidirectional data transfer between masters and slaves
- Multi-master bus (no central master)
- Arbitration between simultaneously transmitting masters without corruption of serial data on the bus
- Serial clock synchronization allowing devices with different bit rates to communicate via one serial bus
- Serial clock synchronization used as a handshake mechanism to suspend and resume serial transfer
- Built-in a 14-bit time-out counter requesting the I²C interrupt if the I²C bus hangs up and timer-out counter overflows.
- Programmable clocks allowing for versatile rate control
- Supports 7-bit addressing mode
- Supports multiple address recognition (four slave address with mask option)
- Supports Power-down Wake-up function (M05xxDN/DE Only)

6.12.3 Basic Configuration

The basic configurations of I²C0 are as follows:

- I²C0 pins are configured on P3_MFP [13:12] register.
- Enable I²C0 clock (I2C0_EN) on APBCLK [8] register.
- Reset I²C0 controller (I2C0_RST) on IPRSTC2 [8] register.

The basic configurations of I²C1 are as follows:

- I²C1 pins are configured on P2_MFP [5:4] or P4_MFP[5:4] registers.
- Enable I²C1 clock (I2C1_EN) on APBCLK [9] register.
- Reset I²C1 controller (I2C1_RST) on IPRSTC2 [9] register.

6.12.4 Functional Description

On I²C bus, data is transferred between a Master and a Slave. Data bits transfer on the SCL and SDA lines are synchronously on a byte-by-byte basis. Each data byte is 8-bit long. There is one SCL clock pulse for each data bit with the MSB being transmitted first, and an acknowledge bit follows each transferred byte. Each bit is sampled during the high period of SCL; therefore, the SDA line may be changed only during the low period of SCL and must be held stable during the high period of SCL. A transition on the SDA line while SCL is high is interpreted as a command (START or STOP). Please refer to the following figure for more detailed I²C BUS Timing.

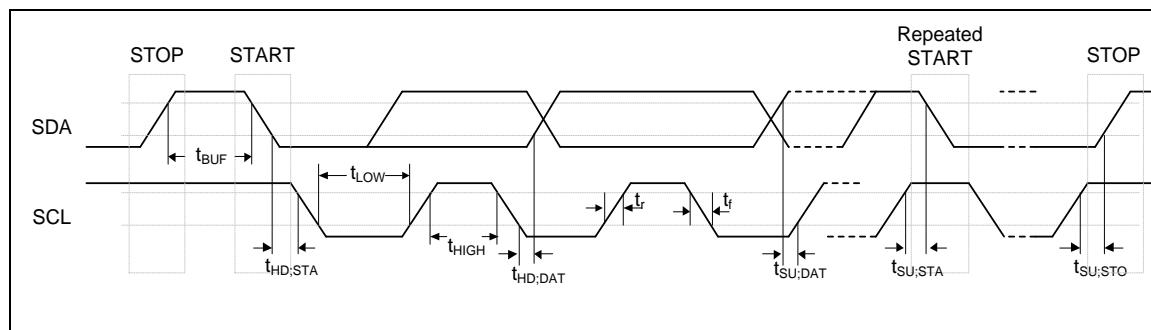

Figure 6-72 I²C Bus Timing

The device's on-chip I²C provides the serial interface that meets the I²C bus standard mode specification. The I²C port handles byte transfers autonomously. To enable this port, the bit ENS1 in I2CON should be set to '1'. The I²C hardware interfaces to the I²C bus via two pins: SDA and SCL. When I/O pins are used as I²C ports, user must set the pins function to I²C in advance.

Note: Pull-up resistor is needed for I²C operation as the SDA and SCL are open-drain pins.

6.12.5 I²C Protocol

The following figure shows the typical I²C protocol. Normally, a standard communication consists of four parts:

- 1) START or Repeated START signal generation
- 2) Slave address and R/W bit transfer
- 3) Data transfer
- 4) STOP signal generation

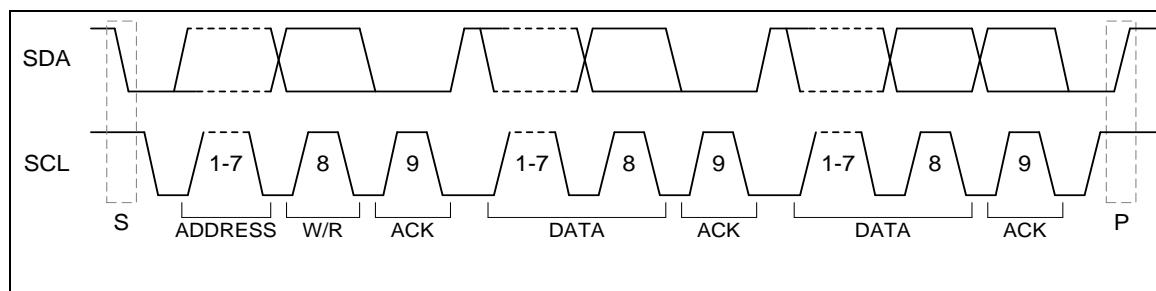

Figure 6-73 I²C Protocol

6.12.5.1 START or Repeated START signal

When the bus is free/idle, meaning no master device is engaging the bus (both SCL and SDA lines are high), a master can initiate a transfer by sending a START signal. A START signal, usually referred to as the “S” bit, is defined as a HIGH to LOW transition on the SDA line while SCL is HIGH. The START signal denotes the beginning of a new data transmission.

A Repeated START is not a STOP signal between two START signals and usually referred to as the “Sr” bit. The master uses this method to communicate with another slave or the same slave in a different transfer direction (e.g. from writing to a device to reading from a device) without releasing the bus.

6.12.5.2 STOP signal

The master can terminate the communication by generating a STOP signal. A STOP signal, usually referred to as the “P” bit, is defined as a LOW to HIGH transition on the SDA line while SCL is HIGH.

The following figure shows the waveform of START, Repeat START and STOP.

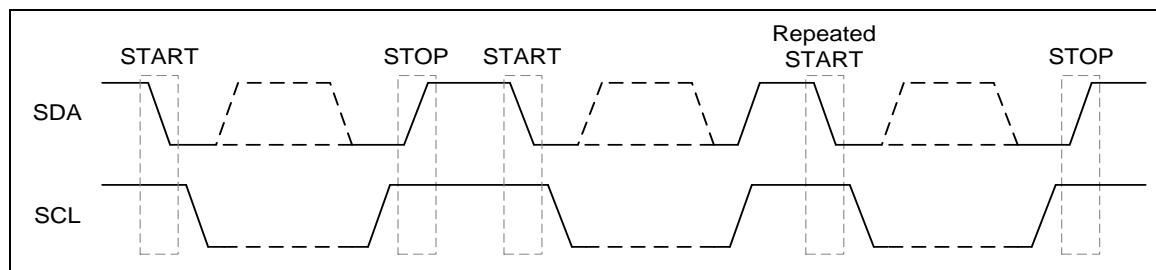

Figure 6-74 START and STOP Conditions

6.12.5.3 Slave Address Transfer

The first byte of data transferred by the master immediately after the START signal is the Slave address (SLA). This is a 7-bit calling address followed by a Read/Write (R/W) bit. The R/W bit signals of the slave indicate the data transfer direction. No two slaves in the system can have the same address. Only the slave with an address that matches the one transmitted by the master will respond by returning an acknowledge bit by pulling the SDA low at the 9th SCL clock cycle.

6.12.5.4 Data Transfer

When a slave receives a correct address with an R/W bit, the data will follow R/W bit specified to transfer. Each transferred byte is followed by an acknowledge bit on the 9th SCL clock cycle. If the slave signals a Not Acknowledge (NACK), the master can generate a STOP signal to abort the data transfer or generate a Repeated START signal and start a new transfer cycle.

If the master, as a receiving device, does Not Acknowledge (NACK) the slave, the slave releases the SDA line for the master to generate a STOP or Repeated START signal.

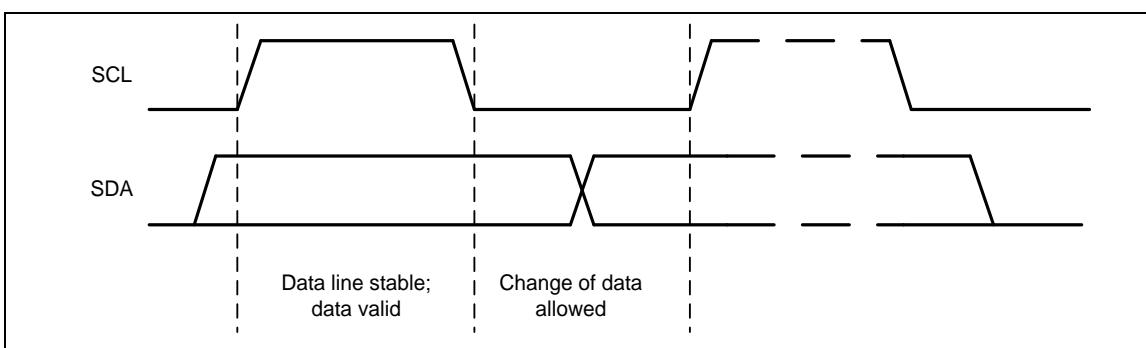

Figure 6-75 Bit Transfer on the I²C Bus

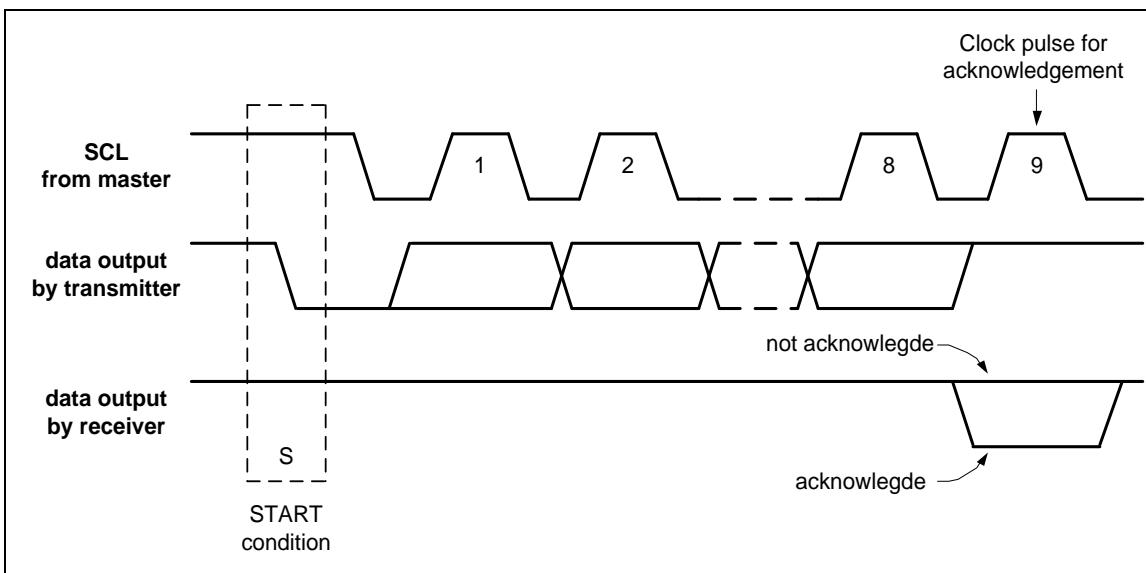

Figure 6-76 Acknowledge on the I²C Bus

6.12.5.5 Data transfer on the I²C bus

The following figure shows a master transmits data to slave. A master addresses a slave with a 7-bit address and 1-bit write index to denote that the master wants to transmit data to the slave. The master keeps transmitting data after the slave returns acknowledge to the master.

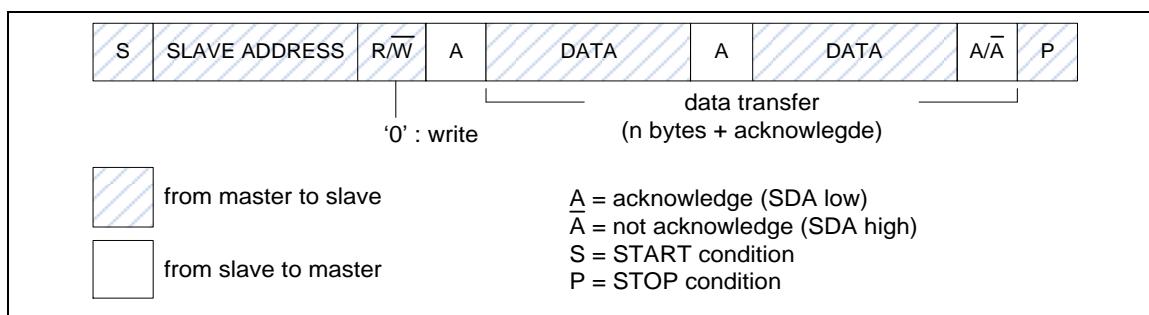

Figure 6-77 Master Transmits Data to Slave

The following figure shows a master read data from slave. A master addresses a slave with a 7-bit address and 1-bit read index to denote that the master wants to read data from the slave. The slave will start transmitting data after the slave returns acknowledge to the master.

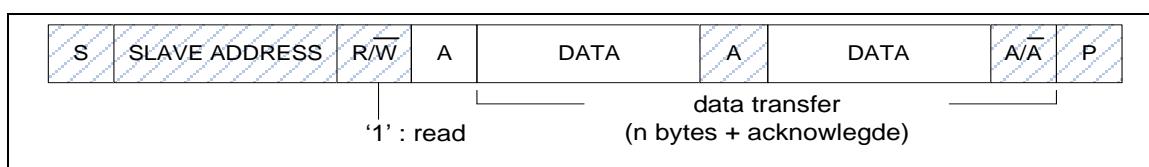

Figure 6-78 Master Reads Data from Slave

6.12.6 I²C Protocol Registers

To control I²C port through the following fifteen special function registers: I2CON (control register), I2CSTATUS (status register), I2CDAT (data register), I2CADDRn (address registers, n=0~3), I2CADMn (address mask registers, n=0~3), I2CLK (clock rate register), I2CTOC (Time-out counter register), I2CWKUPCON(wake-up control register) and I2CWKUPSTS(wake-up status register).

Address Registers (I2CADDR)

The I²C port is equipped with four slave address registers, I2CADDRn (n=0~3). The contents of the register are irrelevant when I²C is in Master mode. In Slave mode, the bit field I2CADDRn[7:1] must be loaded with the chip's own slave address. The I²C hardware will react if the contents of I2CADDRn are matched with the received slave address.

The I²C ports support the “General Call” function. If the GC bit (I2CADDRn [0]) is set the I²C port hardware will respond to General Call address (00H). Clear GC bit to disable general call function.

When the GC bit is set and the I²C is in Slave mode, it can receive the general call address by 00H after Master send general call address to I²C bus, then it will follow status of GC mode.

Slave Address Mask Registers (I2CADM)

The I²C bus controller supports multiple address recognition with four address mask registers I2CADM_n (n=0~3). When the bit in the address mask register is set to 1, it means the received corresponding address bit is "Don't care". If the bit is set to 0, it means the received corresponding register bit should be exactly the same as address register.

Data Register (I2CDAT)

This register contains a byte of serial data to be transmitted or a byte which just has been received. The CPU can be read from or written to the 8-bit (I2CDAT [7:0]) directly while it is not in the process of shifting a byte. When I²C is in a defined state and the serial interrupt flag (SI) is set, data in I2CDAT [7:0] remains stable. While data is being shifted out, data on the bus is simultaneously being shifted in; I2CDAT [7:0] always contains the last data byte presented on the bus.

The acknowledge bit is controlled by the I²C hardware and cannot be accessed by the CPU. Serial data is shifted into I2CDAT [7:0] on the rising edges of serial clock pulses on the SCL line. When a byte has been shifted into I2CDAT [7:0], the serial data is available in I2CDAT [7:0], and the acknowledge bit (ACK or NACK) is returned by the control logic during the ninth clock pulse. In order to monitor bus status while sending data, the bus date will be shifted to I2CDATA[7:0] when sending I2CDATA[7:0] to bus. In the case of sending data, serial data bits are shifted out from I2CDAT [7:0] on the falling edge of SCL clocks, and is shifted to I2CDAT [7:0] on the rising edge of SCL clocks.

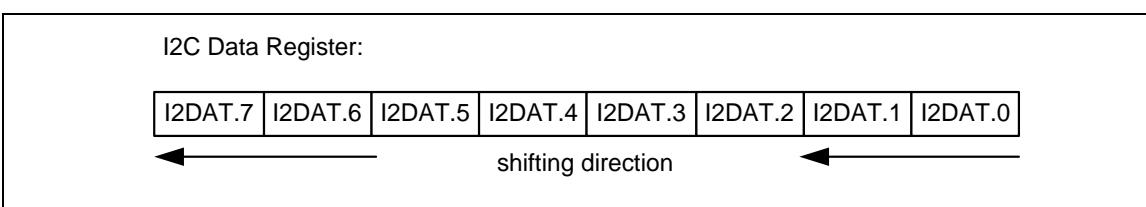

Figure 6-79 I²C Data Shifting Direction

Control Register (I2CON)

The CPU can be read from and written to I2CON [7:0] directly. When the I²C port is enabled by setting ENS1 (I2CON [6]) to high, the internal states will be controlled by I2CON and I²C logic hardware.

There are two bits are affected by hardware: the SI bit is set when the I²C hardware requests a serial interrupt, and the STO bit is cleared when a STOP condition is present on the bus. The STO bit is also cleared when ENS1 = 0.

Once a new status code is generated and stored in I2CSTATUS, the I²C Interrupt Flag bit SI (I2CON [3]) will be set automatically. If the Enable Interrupt bit EI (I2CON [7]) is set at this time, the I²C interrupt will be generated. The bit field I2CSTATUS[7:0] stores the internal state code, the content keeps stable until SI is cleared by software.

Status Register (I2CSTATUS)

I2CSTATUS [7:0] is an 8-bit read-only register. The bit field I2CSTATUS [7:0] contains the status code and there are 26 possible status codes. All states are listed in 0When I2CSTATUS [7:0] is F8H, no serial interrupt is requested. All other I2CSTATUS [7:0] values correspond to the defined I²C states. When each of these states is entered, a status interrupt is requested (SI = 1). A valid status code is present in I2CSTATUS[7:0] one cycle after SI set by hardware and is still present one cycle after SI reset by software.

In addition, the state 00H stands for a Bus Error, which occurs when a START or STOP condition is present at an incorrect position in the I²C format frame. A Bus Error may occur during the serial transfer of an address byte, a data byte or an acknowledge bit. To recover I²C from bus error, STO should be set and SI should be cleared to enter Not Addressed Slave mode. Then STO is cleared to release bus and to wait for a new communication. The I²C bus cannot recognize stop condition during this action when a bus error occurs.

Master Mode		Slave Mode	
STATUS	Description	STATUS	Description
0x08	Start	0xA0	Slave Transmit Repeat Start or Stop
0x10	Master Repeat Start	0xA8	Slave Transmit Address ACK
0x18	Master Transmit Address ACK	0xB0	Slave Transmit Arbitration Lost
0x20	Master Transmit Address NACK	0xB8	Slave Transmit Data ACK
0x28	Master Transmit Data ACK	0xC0	Slave Transmit Data NACK
0x30	Master Transmit Data NACK	0xC8	Slave Transmit Last Data ACK
0x38	Master Arbitration Lost	0x60	Slave Receive Address ACK
0x40	Master Receive Address ACK	0x68	Slave Receive Arbitration Lost
0x48	Master Receive Address NACK	0x80	Slave Receive Data ACK
0x50	Master Receive Data ACK	0x88	Slave Receive Data NACK
0x58	Master Receive Data NACK	0x70	GC mode Address ACK
0x00	Bus error	0x78	GC mode Arbitration Lost
		0x90	GC mode Data ACK
		0x98	GC mode Data NACK
0xF8	Bus Released Note: Status "0xF8" exists in both master/slave modes, and it won't raise interrupt.		

Table 6-20 I²C Status Code Description

Clock Baud Rate Bits (I²CLK)

The data baud rate of I²C is determined by I²CLK [7:0] register when I²C is in Master Mode, and it is not necessary in a Slave mode. In the Slave mode, I²C will automatically synchronize it with any clock frequency from master I²C device.

The data baud rate of I²C setting is Data Baud Rate of I²C = (system clock) / (4x (I²CLK [7:0] +1)). If system clock = 16 MHz, the I²CLK [7:0] = 40 (28H), the data baud rate of I²C = 16 MHz/ (4x (40 +1)) = 97.5 Kbits/sec.

Time-out Counter Register (I²CTOC)

There is a 14-bit time-out counter which can be used to deal with the I²C bus hang-up. If the time-out counter is enabled, the counter starts up counting until it overflows (TIF=1) and generates I²C interrupt to CPU or stops counting by clearing ENTI to 0. When time-out counter is enabled, writing 1 to the SI flag will reset counter and re-start up counting after SI is cleared. If I²C bus hangs up, it causes the I²CSTATUS and flag SI are not updated for a period, the 14-bit time-out counter may overflow and acknowledge CPU the I²C interrupt. Refer to the following figure for the 14-bit time-out counter. User may write 1 to clear TIF to 0.

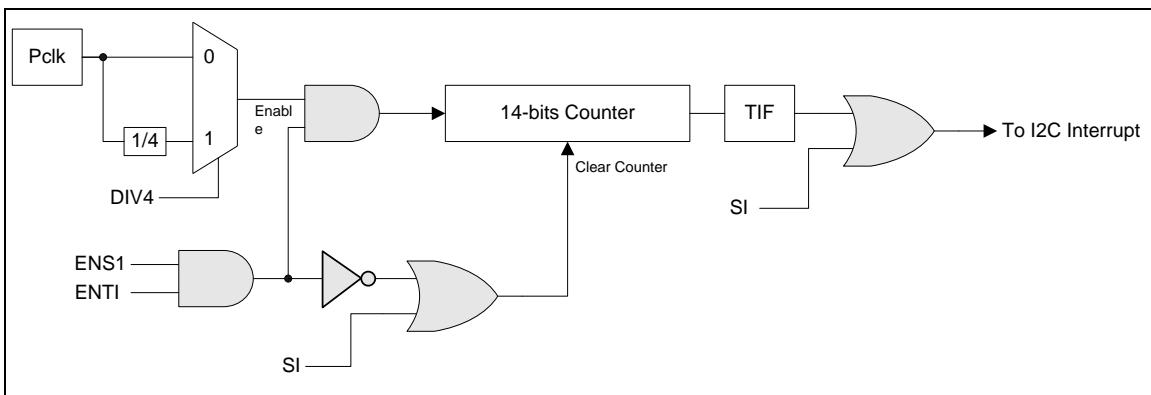

Figure 6-80 I²C Time-out Count Block Diagram

Wake-up Control Register (I²CWKUPCON)

When chip enters Power-down mode, other I²C master can wake-up our chip by addressing our I²C device, user must configure the related setting before entering Sleep mode. When the chip is woken-up by address match with one of the four address register, the following data will be abandoned at this time.

Wake-up Status Register (I²CWKUPSTS)

When system is woken up by other I²C master device, WKUPIF is set to indicate this event. User needs write "1" to clear this bit.

6.12.7 Operation Modes

The on-chip I²C ports support three operation modes, Master, Slave, and General Call Mode.

In a given application, I²C port may operate as a master or as a slave. In Slave mode, the I²C port hardware looks for its own slave address and the general call address. If one of these addresses is detected, and if the slave is willing to receive or transmit data from/to master(by setting the AA bit), acknowledge pulse will be transmitted out on the 9th clock, hence an interrupt is requested on both master and slave devices if interrupt is enabled. When the microcontroller wishes to become the bus master, hardware waits until the bus is free before entering Master mode so that a possible slave action is not be interrupted. If bus arbitration is lost in Master mode, I²C port switches to Slave mode immediately and can detect its own slave address in the same serial transfer.

To control the I²C bus transfer in each mode, user needs to set I2CON, I2CDAT registers according to current status code of I2CSTATUS register. In other words, for each I²C bus action, user needs to check current status by I2CSTATUS register, and then set I2CON, I2CDAT registers to take bus action. Finally, check the response status by I2CSTATUS.

The bits, STA, STO and AA in I2CON register are used to control the next state of the I²C hardware after SI flag of I2CON [3] register is cleared. Upon completion of the new action, a new status code will be updated in I2CSTATUS register and the SI flag of I2CON register will be set. If the I²C interrupt control bit EI (I2CON [7]) is set, appropriate action or software branch of the new status code can be performed in the Interrupt service routine.

The following figure shows the current I²C status code is 0x08, and then set I2CDATA=SLA+W and (STA,STO,SI,AA) = (0,0,1,x) to send the address to I²C bus. If a slave on the bus matches the address and response ACK, the I2CSTATUS will be updated by status code 0x18.

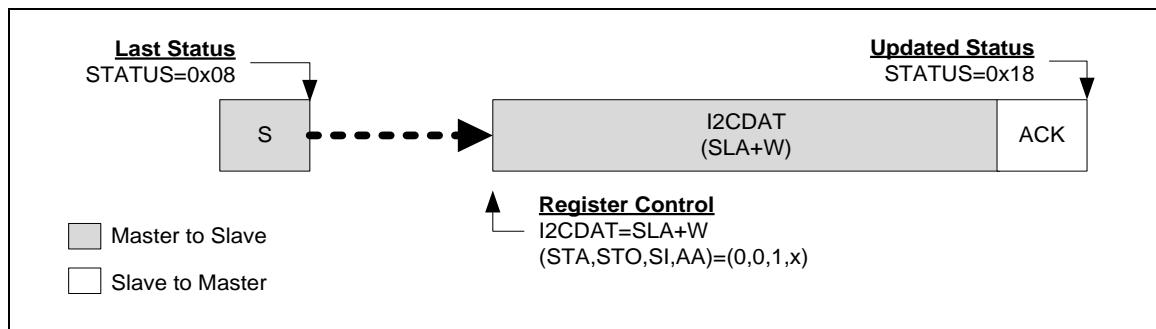

Figure 6-81 Control I²C Bus according to Current I²C Status

6.12.7.1 Master Mode

In below figures, all possible protocols for I²C master are shown. User needs to follow proper path of the flow to implement required I²C protocol.

In other words, user can send a START signal to bus and I²C will be in Master Transmitter mode (Figure 6-82) or Master receiver mode (Figure 6-83) after START signal has been sent successfully and new status code would be 0x08. Followed by START signal, user can send slave address, read/write bit, data and Repeat START, STOP to perform I²C protocol.

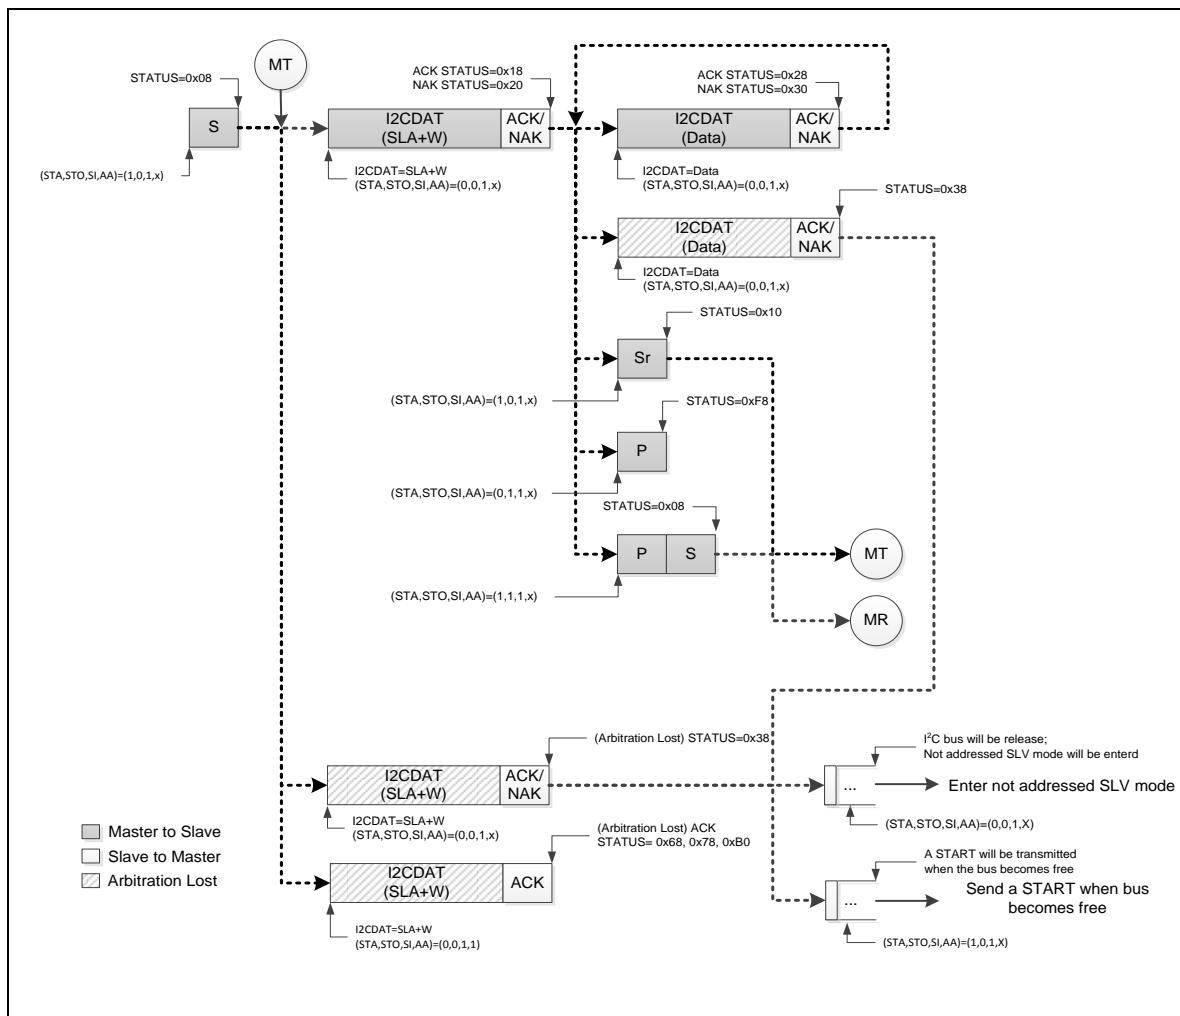

Figure 6-82 Master Transmitter Mode Control Flow

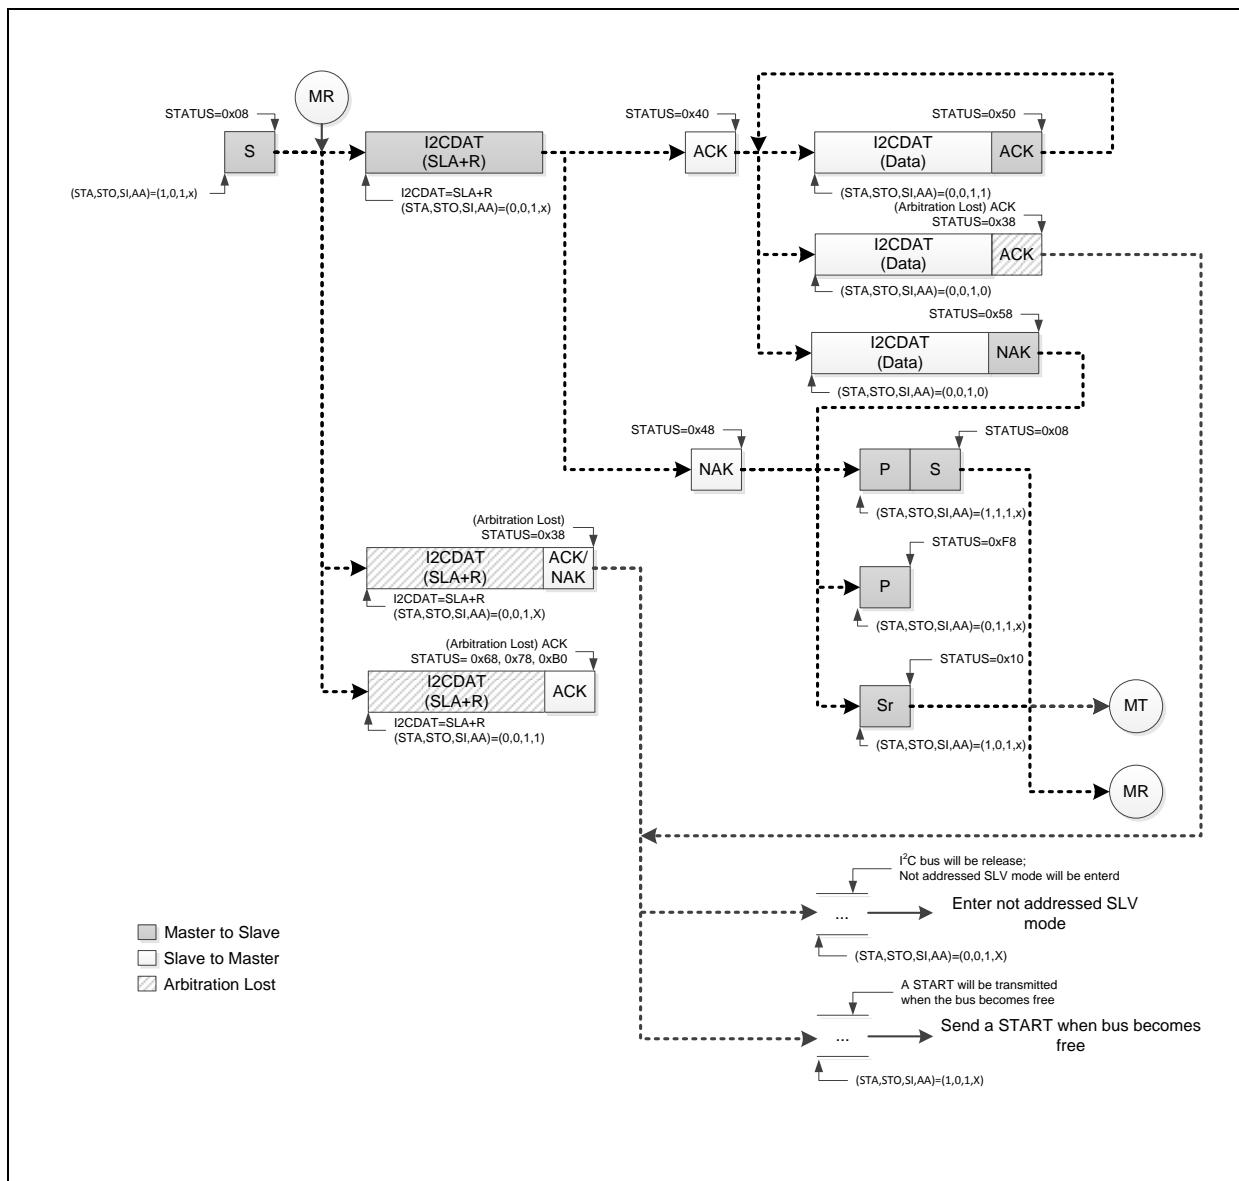

Figure 6-23 Master Receiver Mode Control Flow

If the I²C is in Master mode and gets arbitration lost, the status code will be 0x38. In status 0x38, user may set (STA, STO, SI, AA) = (1, 0, 1, X) to send START to re-start Master operation when bus become free. Otherwise, user may set (STA, STO, SI, AA) = (0, 0, 1, X) to release I²C bus and enter not addressed Slave mode.

6.12.7.2 Slave Mode

When reset default, I²C is not addressed and will not recognize the address on I²C bus. User can set slave address by I2CADDRx and set (STA, STO, SI, AA) = (0, 0, 1, 1) to let I²C recognize the address sent by master. Figure 6-83 shows all the possible flow for I²C in Slave mode. Users need to follow a proper flow (as shown in Figure 6-83) to implement their own I²C protocol.

If bus arbitration is lost in Master mode, I²C port switches to Slave mode immediately and can detect its own slave address in the same serial transfer. If the detected address is SLA+W (Master want to write data to Slave) after arbitration lost, the status code is 0x68. If the detected address is SLA+R (Master want to read data from Slave) after arbitration lost, the status code is 0xB0.

Note: During I²C communication, the SCL clock will be released when writing '1' to clear SI flag in Slave mode.

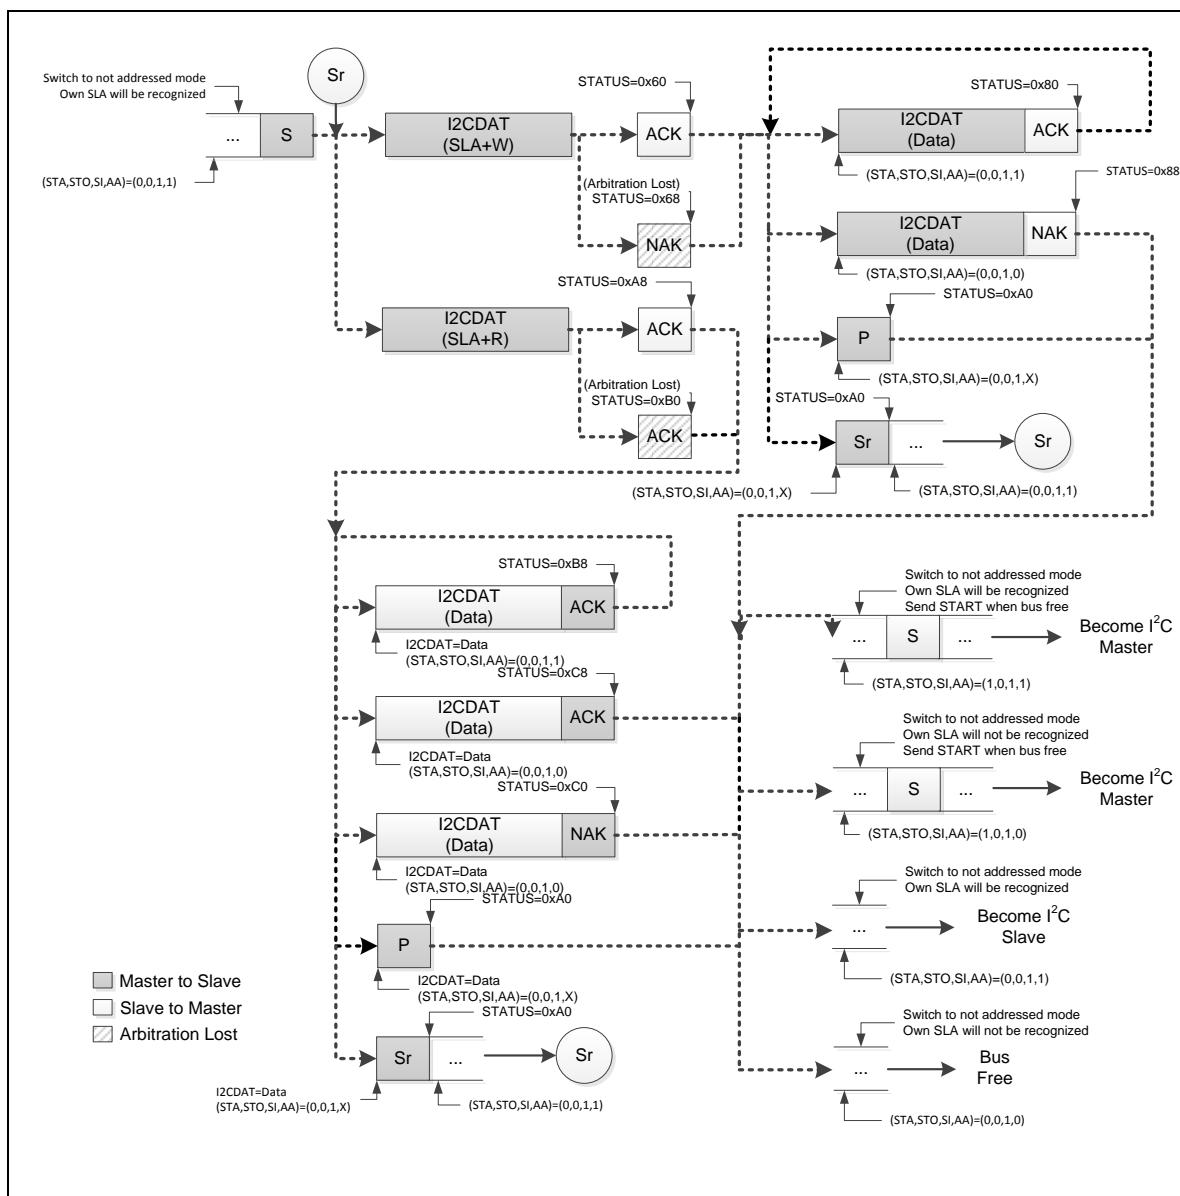

Figure 6-83 Save Mode Control Flow

If I²C is still receiving data in addressed Slave mode but got a STOP or Repeat START, the status code will be 0xA0. User could follow the action for status code 0x88 as shown in the above figure when getting 0xA0 status.

If I²C is still transmitting data in addressed Slave mode but got a STOP or Repeat START, the status code will be 0xA0. User could follow the action for status code 0xC8 as shown in the above figure when getting 0xA0 status.

Note: After slave gets status of 0x88, 0xC8, 0xC0 and 0xA0, slave can switch to not address mode and own SLA will not be recognized. If entering this status, slave will not receive any I²C signal or address from master. At this status, I²C should be reset to leave this status.

6.12.7.3 General Call (GC) Mode

If the GC bit (I2CADDRn [0]) is set, the I²C port hardware will respond to General Call address (00H). User can clear GC bit to disable general call function. When the GC bit is set and the I²C is in Slave mode, it can receive the general call address by 0x00 after master send general call address to I²C bus, then it will follow status of GC mode.

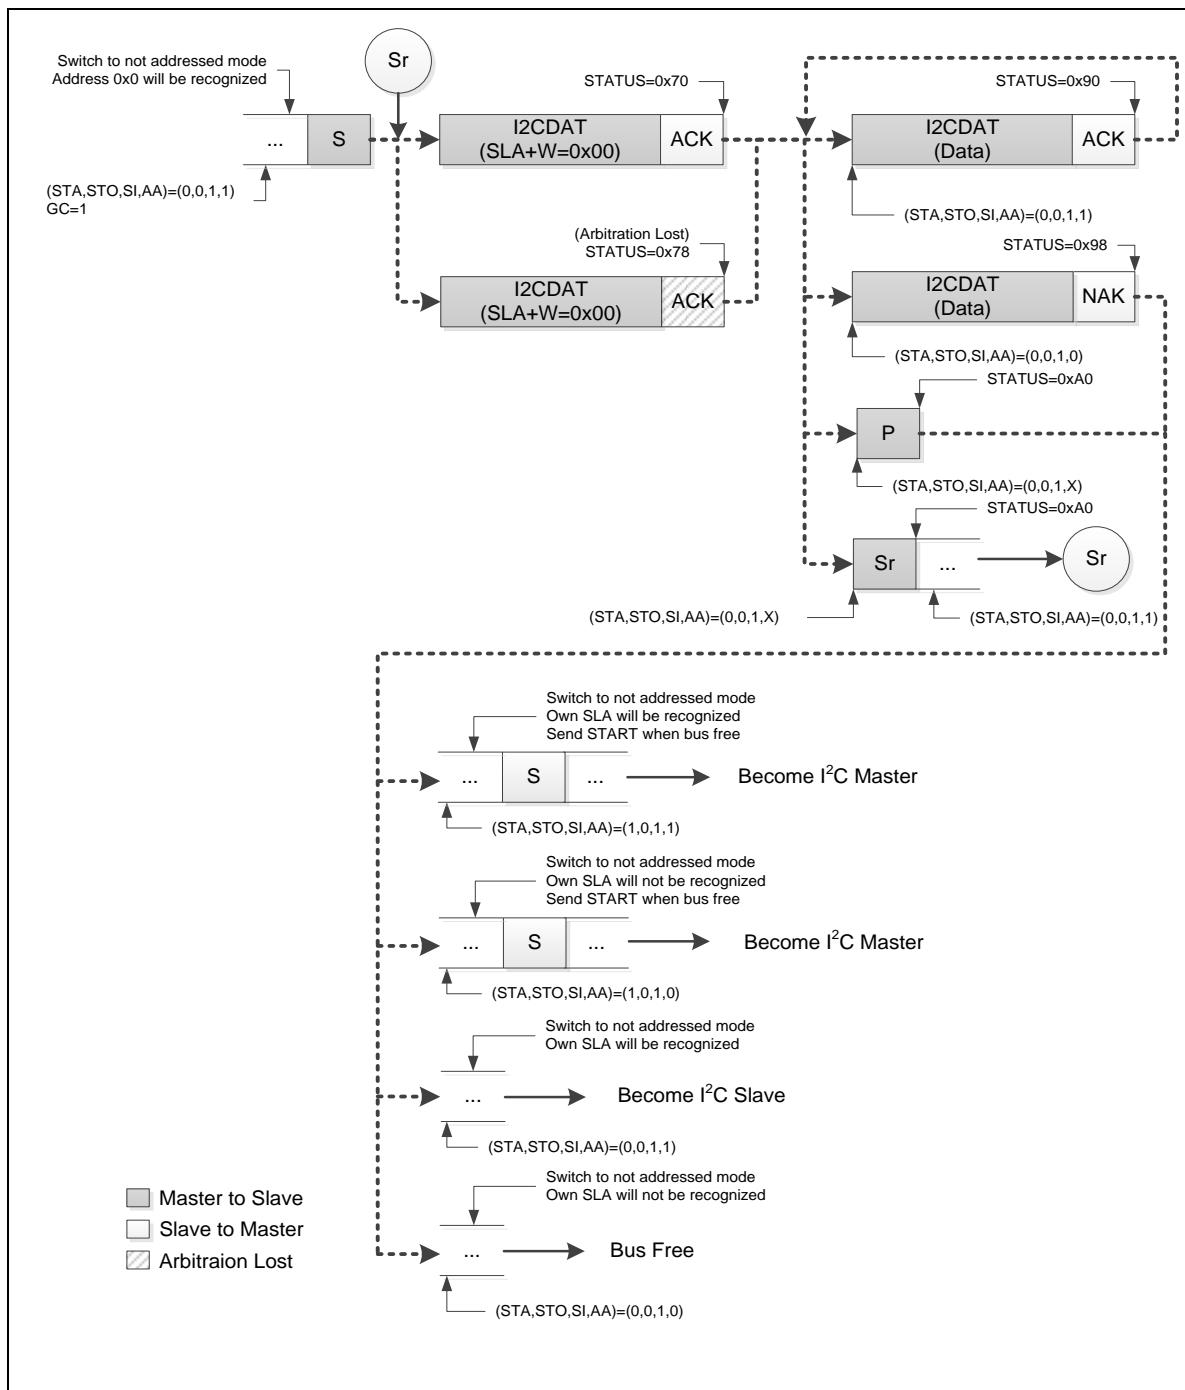

Figure 6-84 GC Mode

If I²C is still receiving data in GC mode but got a STOP or Repeat START, the status code will be 0xA0. User could follow the action for status code 0x98 in above figure when getting 0xA0 status.

Note: After slave gets status of 0x98 and 0xA0, slave can switch to not address mode and own SLA will not be recognized. If entering this status, slave will not receive any I²C signal or address from master. At this time, I²C controller should be reset to leave this status.

6.12.7.4 Multi-Master

In some applications, there are two or more masters on the same I²C bus to access slaves, and the masters may transmit data simultaneously. The I²C in the M05xxBN and M05xxDN/DE supports multi-master by including collision detection and arbitration to prevent data corruption.

- When I2CSTATUS = 0x38, an “Arbitration Lost” is received. Arbitration lost event maybe occur during the send START bit, data bits or STOP bit. User could set (STA, STO, SI, AA) = (1, 0, 1, X) to send START again when bus free, or set (STA, STO, SI, AA) = (0, 0, 1, X) to send STOP to back to not addressed Slave mode.
- When I2CSTATUS = 0x00, a “Bus Error” is received. To recover I²C bus from a bus error, STO should be set and SI should be cleared, and then STO is cleared to release bus.
 - Set (STA, STO, SI, AA) = (0, 1, 1, X) to stop current transfer
 - Set (STA, STO, SI, AA) = (0, 0, 1, X) to release bus

6.12.7.5 Example for Random Read on EEPROM

The following steps are used to configure the I²C related registers when using I²C to read data from EEPROM.

1. Set the multi-function pin in the “GP3_MFP” and “ALT_MFP” registers as SCL and SDA pins.
2. Enable I²C APB clock, I2C_EN=1 in the “APBCLK” register.
3. Set I2C_RST=1 to reset I²C controller then set I²C controller to normal operation, I2C_RST=0 in the “IPRSTC2” register.
4. Set ENS1=1 to enable I²C controller in the “I2CON” register.
5. Give I²C clock a divided register value for I²C clock rate in the “I2CLK”.
6. Set SETENA=0x00040000 in the “NVIC_ISER” register to set I²C IRQ.
7. Set EI=1 to enable I²C Interrupt in the “I2CON” register.
8. Set I²C address registers which are “I2CADDR0~I2CADDR3”.

Random read operation is one of the methods of access EEPROM. The method allows the master to access any address of EEPROM space. The following figure shows the EEPROM random read operation.

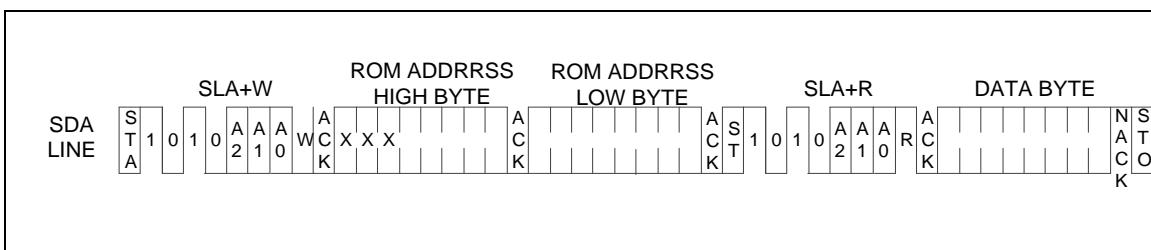

Figure 6-85 EEPROM Random Read

The following figure shows how to use I²C controller to implement the protocol of EEPROM random read.

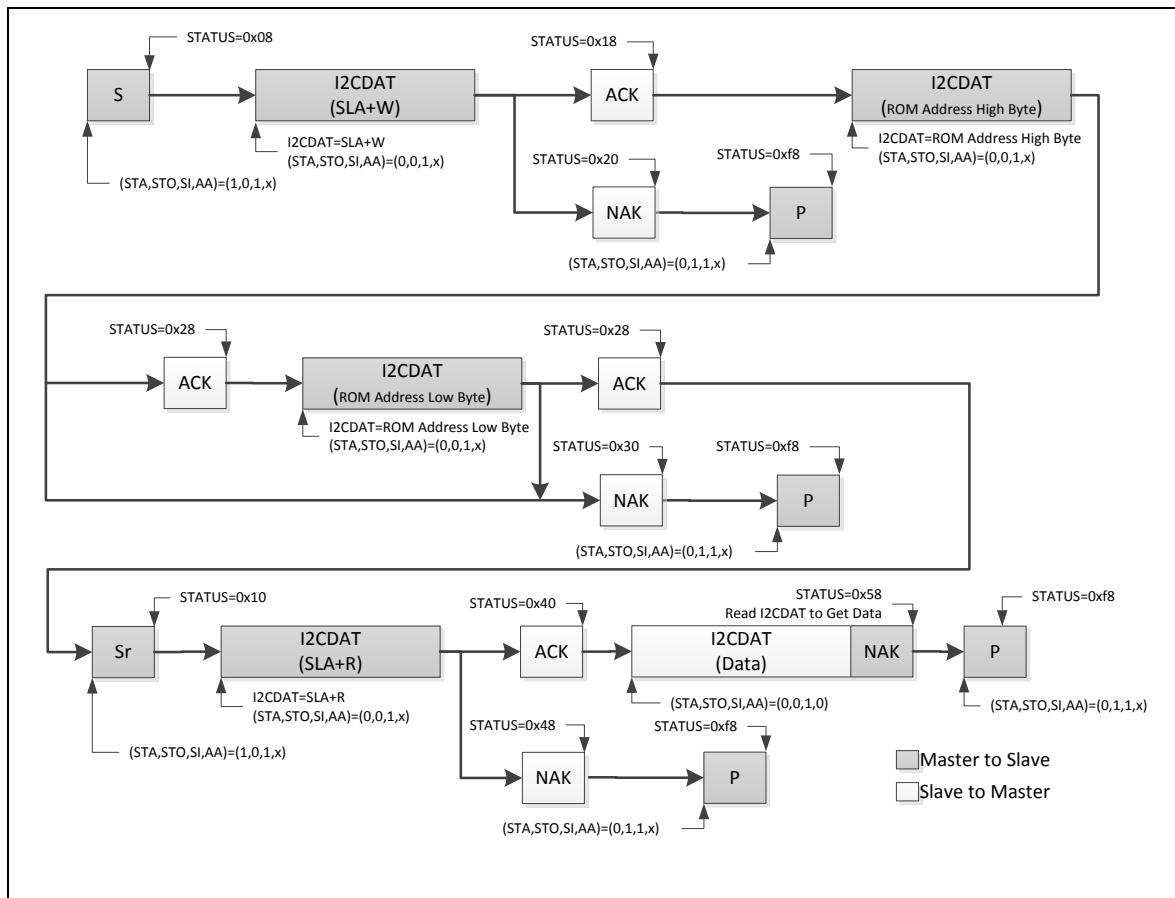

Figure 6-86 Protocol of EEPROM Random Read

The I²C controller sends START to bus to be a master. Then it sends a SLA+W (Slave address + Write bit) to EEPROM followed by two bytes data address to set the EEPROM address to read. Finally, a Repeat START followed by SLA+R is sent to read the data from EEPROM.

6.12.8 Register Map

R: read only, W: write only, R/W: both read and write

Register	Offset	R/W	Description	Reset Value
I²C Base Address:				
I2C0_BA = 0x4002_0000

Bits	Description	
[31:8]	Reserved	Reserved.
[7]	EI	I²C Interrupt Enable Control 0 = I ² C interrupt Disabled. 1 = I ² C interrupt Enabled.
[6]	ENS1	I²C Controller Enable Control 0 = I ² C Controller Disabled. 1 = I ² C Controller Enabled. Set to enable I ² C serial function controller. When ENS1=1 the I ² C serial function enables. The function of multi-function pins must be set to I ² C first.
[5]	STA	I²C START Control Setting STA to logic 1 to enter Master mode, the I ² C hardware sends a START or repeat START condition to bus when the bus is free.
[4]	STO	I²C STOP Control In master mode, setting STO to transmit a STOP condition to bus then I ² C hardware will check the bus condition if a STOP condition is detected this bit will be cleared by hardware automatically. In Slave mode, setting STO resets I ² C hardware to the defined "not addressed" Slave mode. This means it is NO LONGER in the slave receiver mode to receive data from the master transmit device.
[3]	SI	I²C Interrupt Flag When a new I ² C state is present in the I2CSTATUS register, the SI flag is set by hardware, and if bit EI (I2CON [7]) is set, the I ² C interrupt is requested. SI must be cleared by software. Clear SI by writing 1 to it.
[2]	AA	Assert Acknowledge Control When AA=1 prior to address or data received, an acknowledged (low level to SDA) will be returned during the acknowledge clock pulse on the SCL line when 1.) A slave is acknowledging the address sent from master, 2.) The receiver devices are acknowledging the data sent by transmitter. When AA=0 prior to address or data received, a Not acknowledged (high level to SDA) will be returned during the acknowledge clock pulse on

		the SCL line.
[1:0]	Reserved	Reserved.

6.13 Serial Peripheral Interface (SPI)

6.13.1 Overview

The Serial Peripheral Interface (SPI) applies to synchronous serial data communication and allows full-duplex transfer. Devices communicate in Master/Slave mode with 4-wire bi-direction interface. The NuMicro® M051 series contains up to two sets of SPI controllers performing a serial-to-parallel conversion on data received from a peripheral device, and a parallel-to-serial conversion on data transmitted to a peripheral device. Each SPI controller can be configured as a master or a slave device.

6.13.2 Features

- Up to two sets of SPI controllers
- Supports Master or Slave mode operation
- Configurable transfer bit length
- Provides burst mode operation, transmit/receive can be transferred up to two times word transaction in one transfer
- Provides FIFO buffers
- Supports MSB or LSB first transfer
- Supports byte reorder function
- Supports byte or word suspend mode
- Supports two programmable bus clock frequencies in Master mode
- Supports Slave 3-wire mode
- SPI bus clock rate can be configured to equal the system clock rate

6.13.3 Block Diagram

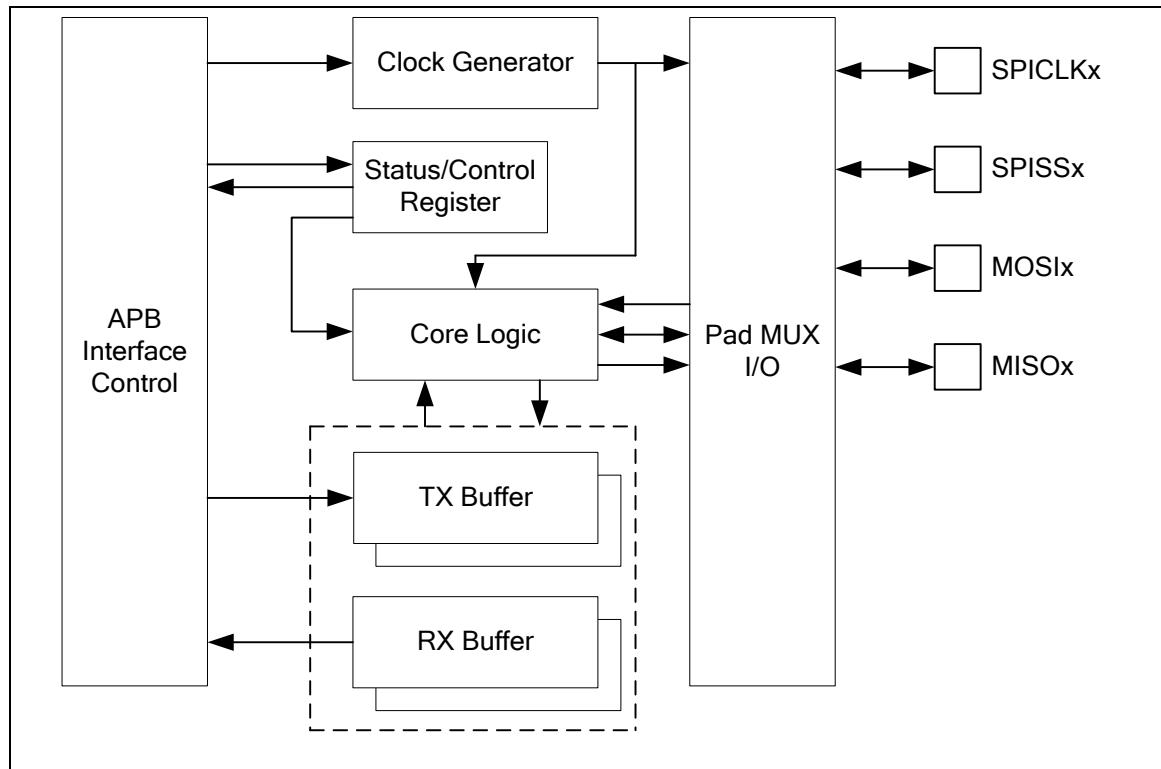

Figure 6-87 SPI Block Diagram

6.13.4 Basic Configuration

The SPI pin functions are configured in P0_MFP and P1_MFP registers. The SPI0 and SPI1 peripheral clock can be enabled in APBCLK[12] and APBCLK[13]. On M05xxDN/DE, the SPI peripheral clock source is selected in CLKSEL1[4] and CLKSEL1[5].

6.13.5 Functional Description

6.13.5.1 Terminology

SPI Peripheral Clock and SPI Bus Clock

The SPI controller needs the SPI peripheral clock to drive the SPI logic unit to perform the data transfer. The SPI bus clock is the clock presented on SPICLKx pin. The SPI clock frequency calculation of M05xxBN is different from that of M05xxDN/DE.

On M05xxBN

In M05xxBN SPI Master mode, the SPI peripheral clock frequency is determined by the setting of DIVIDER (SPI_DIVIDER[15:0]) and DIV_ONE (SPI_CTRL2[0]). If DIV_ONE bit is set to 1, the SPI bus clock frequency is equal to system clock frequency. When the variable bus clock function is disabled, the SPI peripheral clock is equal to the SPI bus clock. M05xxBN SPI supports variable bus clock if the VARCLK_EN bit (SPI_CTL[23]) is set to 1. In this case, the output frequency of bus clock can be programmed as one of the two different frequencies which depends on the value of DIVIDER (SPI_DIVIDER[15:0]) and DIVIDER2 (SPI_DIVIDER[31:16]). The bus clock frequency of each cycle depends on the setting of the SPI_VARCLK register.

In M05xxBN SPI Slave mode, the off-chip master device drives the bus clock through the SPICLK input pin to this SPI controller. The system clock is designated to be the SPI peripheral clock. The SPI peripheral clock rate of slave device must be faster than the SPI bus clock rate 5 times at least.

On M05xxDN/DE

In M05xxDN/DE SPI Master mode and Slave mode, the SPI peripheral clock frequency is determined by the settings of clock source, BCn (SPI_CTRL2[31]) option and clock divisor (SPI_DIVIDER[7:0]). The SPIx_S bit of CLKSEL1 register determines the clock source of the SPI peripheral clock. The clock source can be HCLK or PLL output clock. Set the BCn bit to 0 for the compatible SPI clock frequency calculation of previous products. The DIVIDER setting of SPI_DIVIDER register determines the divisor of the clock frequency calculation.

In M05xxDN/DE SPI Master mode, the SPI peripheral clock is equal to the SPI bus clock.

In M05xxDN/DE SPI Slave mode, the SPI bus clock is provided by an off-chip master device. The SPI peripheral clock frequency of slave device must be faster than the bus clock frequency of the master device connected together. The frequency of SPI peripheral clock cannot be faster than the APB clock frequency regardless of Master mode or Slave mode.

Master/Slave Mode

This SPI controller can be set as Master or Slave mode by setting the SLAVE bit (SPI_CTRL[18]) to communicate with the off-chip SPI slave or master device. The application block diagrams in Master or Slave mode are shown below.

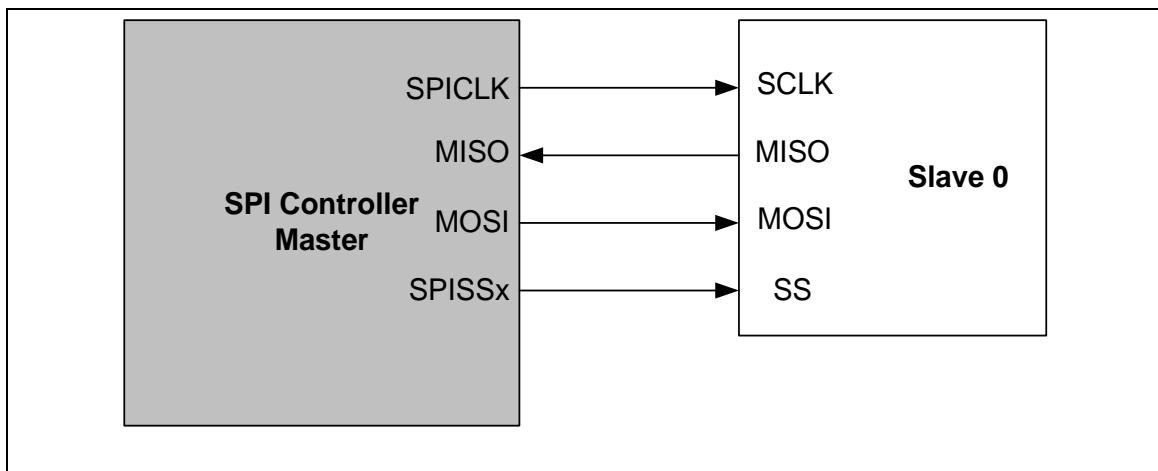

Figure 6-88 SPI Master Mode Application Block Diagram

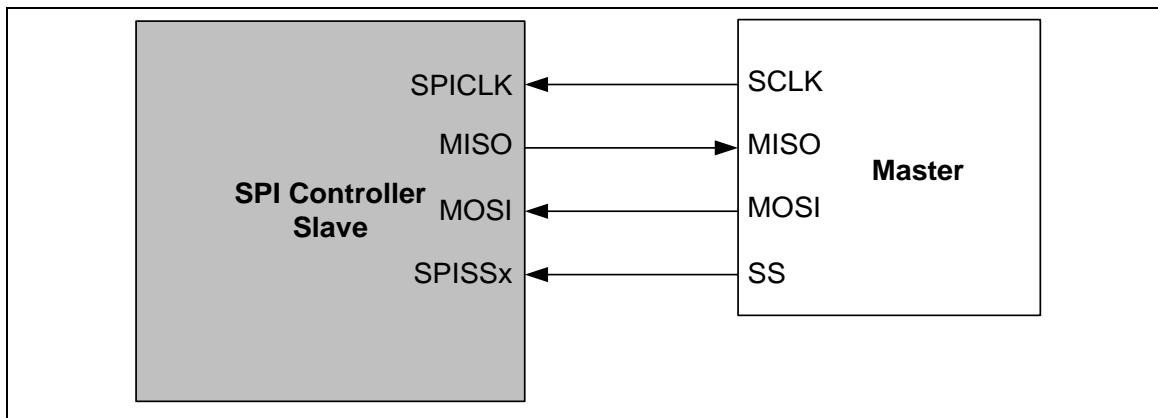

Figure 6-89 SPI Slave Mode Application Block Diagram

Clock Polarity

The CLKP bit (SPI_CTL[11]) defines the bus clock idle state. If CLKP = 1, the output SPICLK is idle at high state, otherwise it is at low state if CLKP = 0.

Transmit/Receive Bit Length

The bit length of a transaction word is defined in TX_BIT_LEN bit field (SPI_CCTRL[7:3]). It can be configured up to 32-bit length in a transaction word for transmitting and receiving.

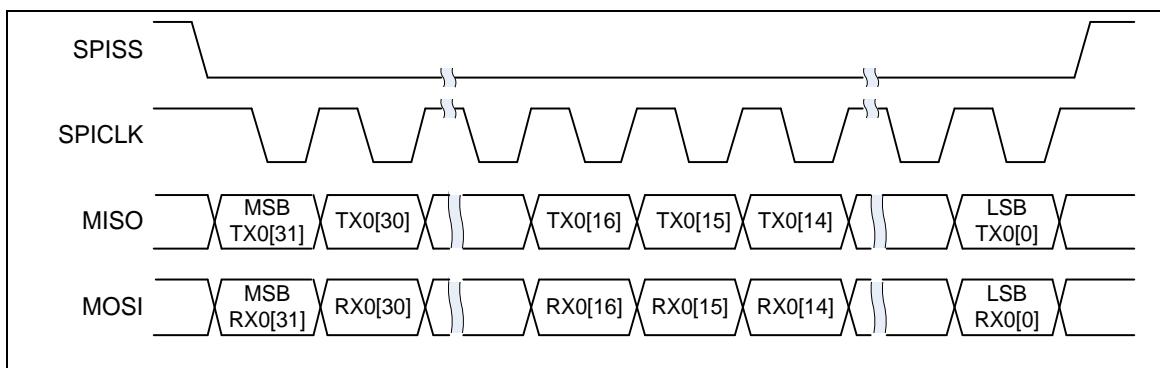

Figure 6-90 32-bit in One Transaction

LSB First

The LSB bit (SPI_CNTRL[10]) defines the data transmission either from LSB or MSB firstly to start to transmit/receive data.

Transmit Edge

The TX_NEG bit (SPI_CNTRL[2]) defines the data transmitted out either on negative edge or on positive edge of bus clock SPICLK.

Receive Edge

The Rx_NEG bit (SPI_CNTRL[1]) defines the data received in either on negative edge or on positive edge of bus clock SPICLK.

Note: The settings of TX_NEG and RX_NEG are mutual exclusive. In other words, don't transmit and receive data at the same clock edge.

Word Suspend

The four bits field of SP_CYCLE (SPI_CNTRL[15:12]) provide a configurable suspend interval between two successive transaction words in Master mode. The definition of the suspend interval is the interval between the last clock edge of the preceding transaction word and the first clock edge of the following transaction word.

On M05xxBN, the default value of SP_CYCLE is 0x0 (2 bus clock cycles), and the SP_CYCLE setting will not take effect on data transfer process if TX_NUM is set to 0x00. On M05xxDN/DE, the default value of SP_CYCLE is 0x3 (3.5 bus clock cycles), and the SP_CYCLE setting will not take effect to the word suspend interval if software disables the FIFO mode.

Slave Selection

In Master mode, each SPI controller can drive one off-chip slave device through the slave select output pin, SPISSx. In Slave mode, the off-chip master device drives the slave select signal from the SPISSx input pin to this SPI controller. In Master/Slave mode, the active state of slave select signal can be programmed to low active or high active in SS_LVL bit (SPI_SSR[2]), and the SS_LTRIG bit (SPI_SSR[4]) defines the slave select signal SPISSx is level trigger or edge trigger. The selection of trigger condition depends on what type of peripheral slave/master device is connected.

In Slave mode, if the SS_LTRIG bit is configured as level trigger, the LTRIG_FLAG bit (SPI_SSR[5]) is used to indicate if both the number of received data and the number of received bits meet the requirement which defined in TX_NUM and TX_BIT_LEN among one transaction done (the transaction done means the unit transfer interrupt flag is set to 1 when the slave select signal is inactivated or the SPI controller finishes one data transfer.)

Level-trigger / Edge-trigger

In Slave mode, the slave select signal can be configured as level-trigger or edge-trigger. In edge-trigger, the data transfer starts from an active edge of the slave select signal and ends on an inactive edge of the slave select signal. The unit-transfer interrupt flag (SPI_CNTRL[16]) will be set to 1 as an inactive edge is detected. If master does not send an inactive edge to slave, the transfer procedure will not be completed and the unit-transfer interrupt flag of slave will not be set. In level-trigger, the unit-transfer interrupt flag of slave will be set when one of the following two conditions occurs. The first condition is that if the number of transferred bits matches the settings of TX_NUM and TX_BIT_LEN, the unit-transfer interrupt flag of slave will be set. The TX_NUM setting is not available on M05xxDN/DE, only the setting of TX_BIT_LEN will be considered. The second condition, if master set the slave select pin to inactive level during the transfer in progress, it will force slave device to terminate the current transfer no matter how many bits have been transferred and the unit-transfer interrupt flag will be set. User can read the status of LTRIG_FLAG bit to check if the data has been completely transferred.

6.13.5.2 Automatic Slave Selection

In Master mode, if the AUTOSS bit (SPI_SSR[3]) is set, the slave select signal will be generated automatically and output to SPISSx pin according to SSR bit (SPI_SSR[0]) whether be enabled or not. This means that the slave select signal will be asserted by the SPI controller when data transfer is started by setting the GO_BUSY bit (SPI_CNTRL[0]) and will be de-asserted after the data transfer is finished. If the AUTOSS bit is cleared, the slave select output signal will be asserted/de-asserted by setting/clearing the SSR bit. The active state of the slave select output signal is specified in SS_LVL bit (SPI_SSR[2]).

6.13.5.3 Variable Bus Clock Frequency (M05xxBN Only)

In Master mode, if the VARCLK_EN bit (SPI_CNTRL[23]) is set to 1, the output of SPI bus clock can be programmed as variable frequency pattern. The SPI bus clock period of each cycle depends on the setting of the SPI_VARCLK register. When the variable clock function is enabled, the TX_BIT_LEN setting must be set as 0x10 to configure the data transfer as 16-bit transfer mode. The SPI_VARCLK[31] determines the clock period of the first clock cycle. If SPI_VARCLK[31] is 0, the first clock cycle depends on the DIVIDER setting; if it is 1, the first clock cycle depends on the DIVIDER2 setting. Two successive bits in VARCLK[30:1] defines one clock cycle. If the two successive bits are 00, the clock cycle depends on the DIVIDER setting; if they are 11, the clock cycle depends on the DIVIDER2 setting. The bit field VARCLK[30:29] defines the second clock cycle of SPI bus clock of a transaction, and the bit field VARCLK[28:27] defines the third clock cycle, and so on. The VARCLK[0] has no meaning. The following figure shows the timing relationship among the SPI bus clock, VARCLK setting, DIVIDER setting and DIVIDER2 setting.

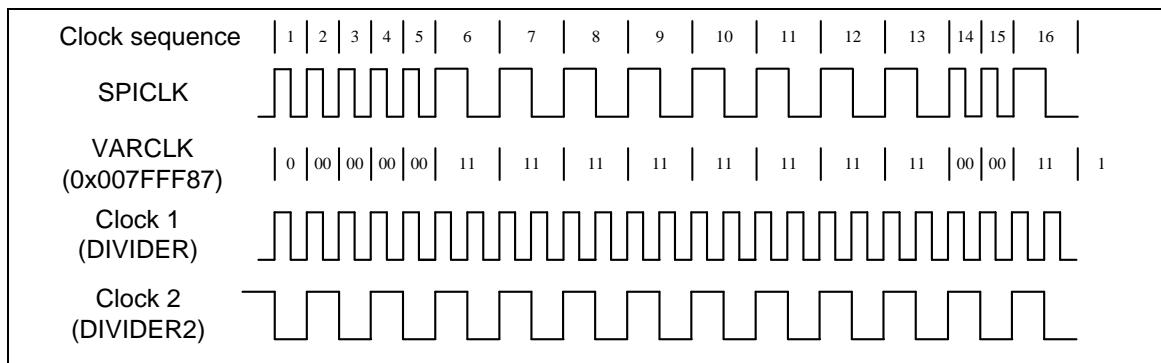

Figure 6-91 Variable Bus Clock Frequency

6.13.5.4 Burst Mode (M05xxBN Only)

The SPI controller can switch to Burst mode by setting TX_NUM bit field (SPI_CNTRL[9:8]) to 0x01. In burst mode, SPI can transmit/receive two transactions in one transfer. The bit length of each transaction is determined by TX_BIT_LEN bit field. The SPI burst mode waveform is shown below:

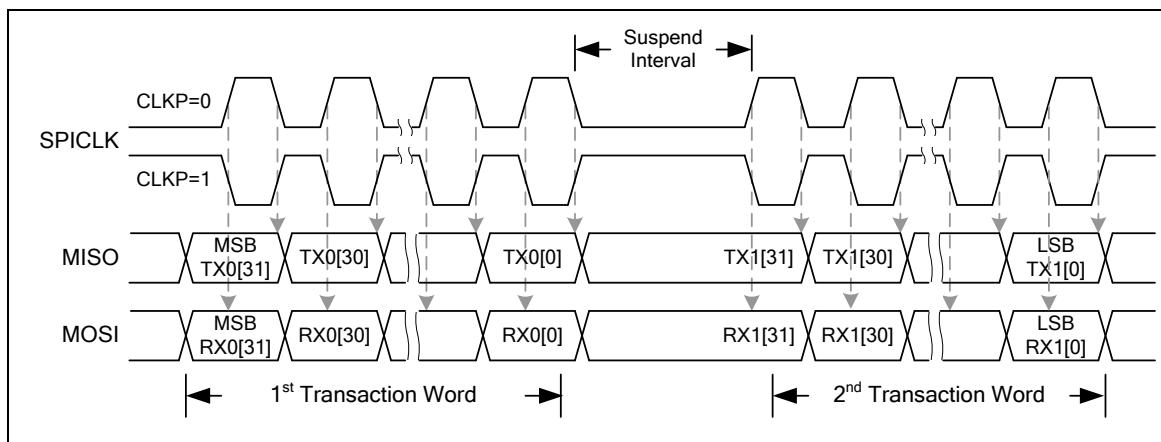

Figure 6-92 Two Transactions in One Transfer (Burst Mode)

6.13.5.5 Byte Reorder Function

When the transfer is set as MSB first (LSB = 0) and the byte reorder function is enabled, the data stored in the TX buffer and RX buffer will be rearranged in the order as [Byte0, Byte1, Byte2, Byte3] when the bit length is configured as 32-bit (TX_BIT_LEN=0). The sequence of transmitted/received data will be Byte0, Byte1, Byte2, and then Byte3. If the TX_BIT_LEN bit field is set to 24, the data in TX buffer and RX buffer will be rearranged as [unknown byte, Byte0, Byte1, Byte2]. The SPI controller will transmit/receive data with the sequence of Byte0, Byte1 and then Byte2. Each byte will be transmitted/received with MSB first. The rule of 16-bit mode is the same as above. Byte reorder function is only available when TX_BIT_LEN is configured as 16, 24, or 32 bits.

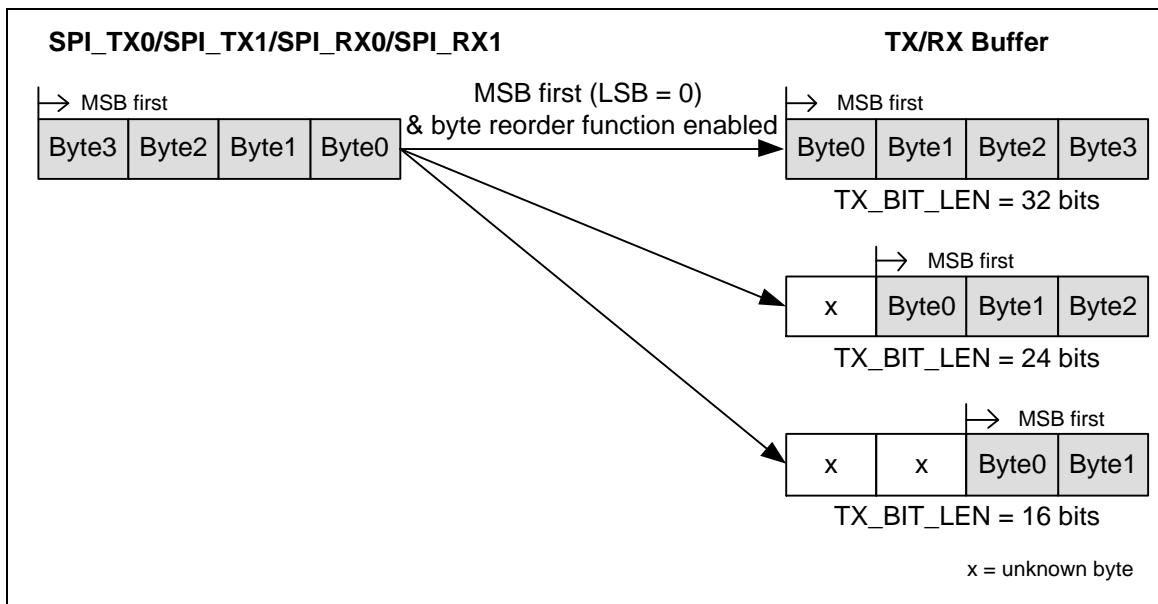

Figure 6-93 Byte Reorder

6.13.5.6 Byte Suspend Function

Both settings of byte suspend interval and word suspend interval are configured in SP_CYCLE.

In M05xxBN Master mode, if SPI_CNTRL[19] is set to 1, the hardware will insert a suspend interval 2 ~ 17 bus clock periods between two successive bytes in a transaction word. Note that when enabling the byte suspend function, the setting of TX_BIT_LEN must be configured as 32 bits only.

In M05xxDN/DE Master mode, if the byte reorder function is enabled by setting SPI_CNTRL[19] to 1, the hardware will insert a suspend interval of 0.5 ~ 15.5 bus clock periods between two successive bytes in a transaction word. The setting of TX_BIT_LEN can be configured as 16, 24 or 32 bits.

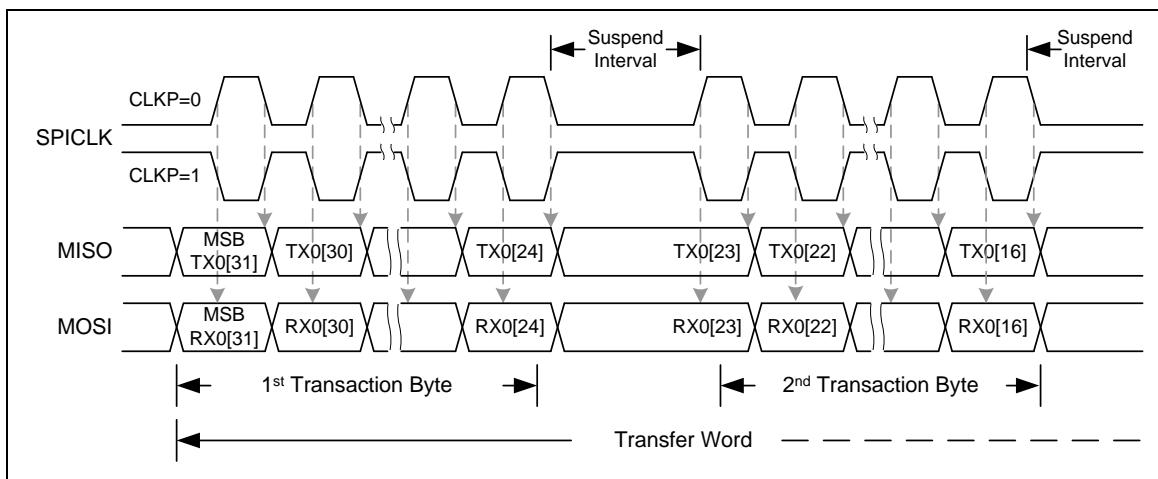

Figure 6-94 Timing Waveform for Byte Suspend

REORDER	Description
00	Disable both byte reorder function and byte suspend interval.
01	Enable byte reorder function and insert a byte suspend internal (2~17 SPICLK) among each byte. The setting of TX_BIT_LEN must be configured as 0x00 (32 bits/ word)
10	Enable byte reorder function but disable byte suspend function
11	Disable byte reorder function, but insert a suspend interval (2~17 SPICLK) among each byte. The setting of TX_BIT_LEN must be configured as 0x00 (32 bits/ word)

Table 6-22 Byte Order and Byte Suspend Configurations on M05xxBN

6.13.5.7 Slave 3-wire Mode

When the NOSLVSEL bit (SPI_CNTRL2[8]) is set by software to enable the Slave 3-wire mode, the SPI controller can work with no slave select signal in Slave mode. The NOSLVSEL bit only takes effect in Slave mode. Only three pins, SPICLK, MISO, and MOSI, are required to communicate with a SPI master. The SPISS pin can be configured as a GPIO. When the NOSLVSEL bit is set to 1, the SPI slave will be ready to transmit/receive data after the GO_BUSY bit is set to 1. As the number of received bits meets the requirement which defined in TX_BIT_LEN and TX_NUM, the unit-transfer interrupt flag, IF (SPI_CNTRL[16]), will be set to 1.

Note: In Slave 3-wire mode, the SS_LTRIG bit (SPI_SSR[4]) should be set as 1.

6.13.5.8 FIFO Mode (M05xxDN/DE Only)

The SPI controllers support FIFO mode when the FIFO bit, SPI_CNTRL[21], is set as 1. The SPI controllers equip with four 32-bit wide transmit and receive FIFO buffers.

The transmit FIFO buffer is a 4-layer depth, 32-bit wide, first-in, first-out register buffer. The software can write data to the transmit FIFO buffer by writing the SPI_TX0 register. The data stored in the transmit FIFO buffer will be read and sent out by the transmission control logic. If the 4-layer transmit FIFO buffer is full, the TX_FULL bit will be set to 1. When the SPI transmission logic unit draws out the last datum of the transmit FIFO buffer, so that the 4-layer transmit FIFO buffer is empty, the TX_EMPTY bit will be set to 1. Note that the TX_EMPTY flag is set to 1 while the last transaction is still in progress.

The received FIFO buffer is also a 4-layer depth, 32-bit wide, first-in, first-out register buffer. The receive control logic will store the received data to this buffer. The software can read the FIFO buffer data from SPI_RX0 register. There are FIFO related status bits, like RX_EMPTY and RX_FULL, to indicate the current status of FIFO buffer.

In FIFO mode, the software can set the transmitting and receiving threshold by setting the TX_THRESHOLD and RX_THRESHOLD settings. When the count of valid data stored in transmit FIFO buffer is less than or equal to TX_THRESHOLD setting, the TX_INTSTS bit will be set to 1. When the count of valid data stored in receive FIFO buffer is larger than RX_THRESHOLD setting, the RX_INTSTS bit will be set to 1.

In FIFO mode, the software can write 4 data to the SPI transmit FIFO buffer in advance. When the SPI controller operates with FIFO mode, the GO_BUSY bit of SPI_CNTRL register will be controlled by hardware, software should not modify the content of SPI_CNTRL register unless

clearing the FIFO bit to disable the FIFO mode.

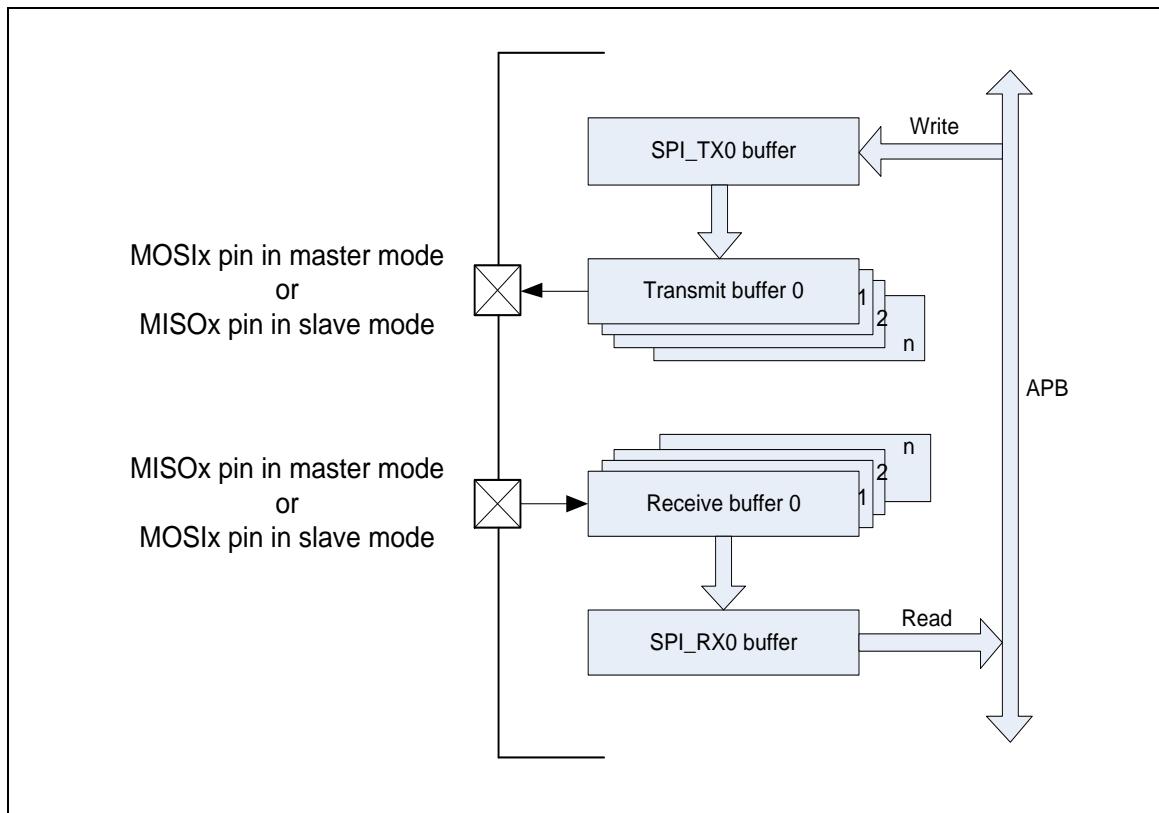

Figure 6-95 FIFO Mode Block Diagram

In Master mode transmission operation, the TX_EMPTY flag will be cleared to 0 when the FIFO bit is set to 1 and the software write the first datum to the SPI_TX0 register. The transmission starts immediately as long as the transmit FIFO buffer is not empty. User can write the next data into SPI_TX0 register immediately. The SPI controller will insert a suspend interval between two successive transactions in FIFO mode and the period of suspend interval is decided by the setting of SP_CYCLE (SPI_CNTRL [15:12]). User can write data into SPI_TX0 register as long as the TX_FULL flag is 0.

The subsequent transactions will be triggered automatically if the transmitted data are updated in time. If the SPI_TX0 register is not updated after all data transfer are done, the transfer will stop.

In Master mode reception operation, the serial data are received from MISOx pin and stored to receive FIFO buffer. The RX_EMPTY flag will be cleared to 0 while the receive FIFO buffer contain unread data. The software can read the received data from SPI_RX0 register as long as the RX_EMPTY flag is 0. If the receive FIFO buffer contain 4 unread data, the RX_FULL flag will be set to 1. The SPI controller will stop receiving data until the software read the SPI_RX0 register.

In Slave mode, when the FIFO bit is set as 1, the GO_BUSY bit will be set as 1 by hardware automatically. If user wants to stop the Slave mode SPI data transfer, both the FIFO bit and GO_BUSY bit must be cleared to 0 by software.

In Slave mode transmission operation, when the software writes data to SPI_TX0 register, the data will be loaded into transmit FIFO buffer and the TX_EMPTY flag will be set to 0. The transmission will start when the slave device receives clock signal from master. The software can write data to SPI_TX0 register as long as TX_FULL flag is 0. After all data have been drawn out by the SPI transmission logic unit and the software does not update the SPI_TX0 register, the TX_EMPTY flag will be set to 1.

In Slave mode reception operation, the serial data is received from MOSIx pin and stored to SPI_RX0 register. The reception mechanism is similar to Master mode reception operation.

6.13.5.9 Interrupt

SPI unit-transfer interrupt

As the SPI controller finishes a unit transfer, the unit-transfer interrupt flag IF (SPI_CCTRL[16]) will be set to 1. The unit-transfer interrupt event will generate an interrupt to CPU if the unit-transfer interrupt enable bit IE (SPI_CCTRL[17]) is set. The unit-transfer interrupt flag can be cleared only by writing 1 to it.

SPI Slave 3-wire mode start interrupt

In Slave 3-wire mode, the Slave 3-wire mode start interrupt flag, SLV_START_INTSTS (SPI_CCTRL2[11]), will be set to 1 when the slave senses the SPI bus clock signal. The SPI controller will issue an interrupt if the SSTA_INTEN bit (SPI_CCTRL2[10]) is set to 1. If the count of the received bits is less than the bit length setting of TX_BIT_LEN and there is no more SPI bus clock input over the expected time period which is defined by user, user can set the SLV_ABORT bit (SPI_CCTRL2[9]) to abort the current transfer. The unit-transfer interrupt flag, IF, will be set to 1 if the SLV_ABORT bit is set to 1 by software.

Receive FIFO time-out interrupt (M05xxDN/DE Only)

In FIFO mode, there is time-out function to inform user. If there is a received data in the FIFO and it does not get read by software over 64 SPI peripheral clock periods in Master mode or over 576 SPI peripheral clock periods in Slave mode, it will send a time-out interrupt to the system if the time-out interrupt enable bit, FIFO_CTL[21], is set to 1.

Transmit FIFO interrupt (M05xxDN/DE Only)

In FIFO mode, if the valid data count of the transmit FIFO buffer is less than or equal to the setting value of TX_THRESHOLD, the transmit FIFO interrupt flag will be set to 1. The SPI controller will generate a transmit FIFO interrupt to the system if the transmit FIFO interrupt enable bit, SPI_FIFO_CTL[3], is set to 1.

Receive FIFO interrupt (M05xxDN/DE Only)

In FIFO mode, if the valid data count of the receive FIFO buffer is larger than the setting value of RX_THRESHOLD, the receive FIFO interrupt flag will be set to 1. The SPI controller will generate a receive FIFO interrupt to the system if the receive FIFO interrupt enable bit, SPI_FIFO_CTL[2], is set to 1.

6.13.6 Timing Diagram

The active state of slave select signal can be defined by the settings of SS_LVL bit (SPI_SSR[2]) and SS_LTRIG bit (SPI_SSR[4]). The bus clock (SPICLK) idle state can be configured as high state or low state by setting the CLKP bit (SPI_CNTRL[11]). It also provides the bit length of a transaction word in TX_BIT_LEN bit field (SPI_CNTRL[7:3]), the transaction number in TX_NUM bit field (SPI_CNTRL[9:8]), and transmit/receive data from MSB or LSB first in LSB bit (SPI_CNTRL[10]). User also can select which edge of bus clock to transmit/receive data in TX_NEG/RX_NEG (SPI_CNTRL[2]/SPI_CNTRL[1]) bit. Four SPI timing diagrams for master/slave operations and the related settings are shown below.

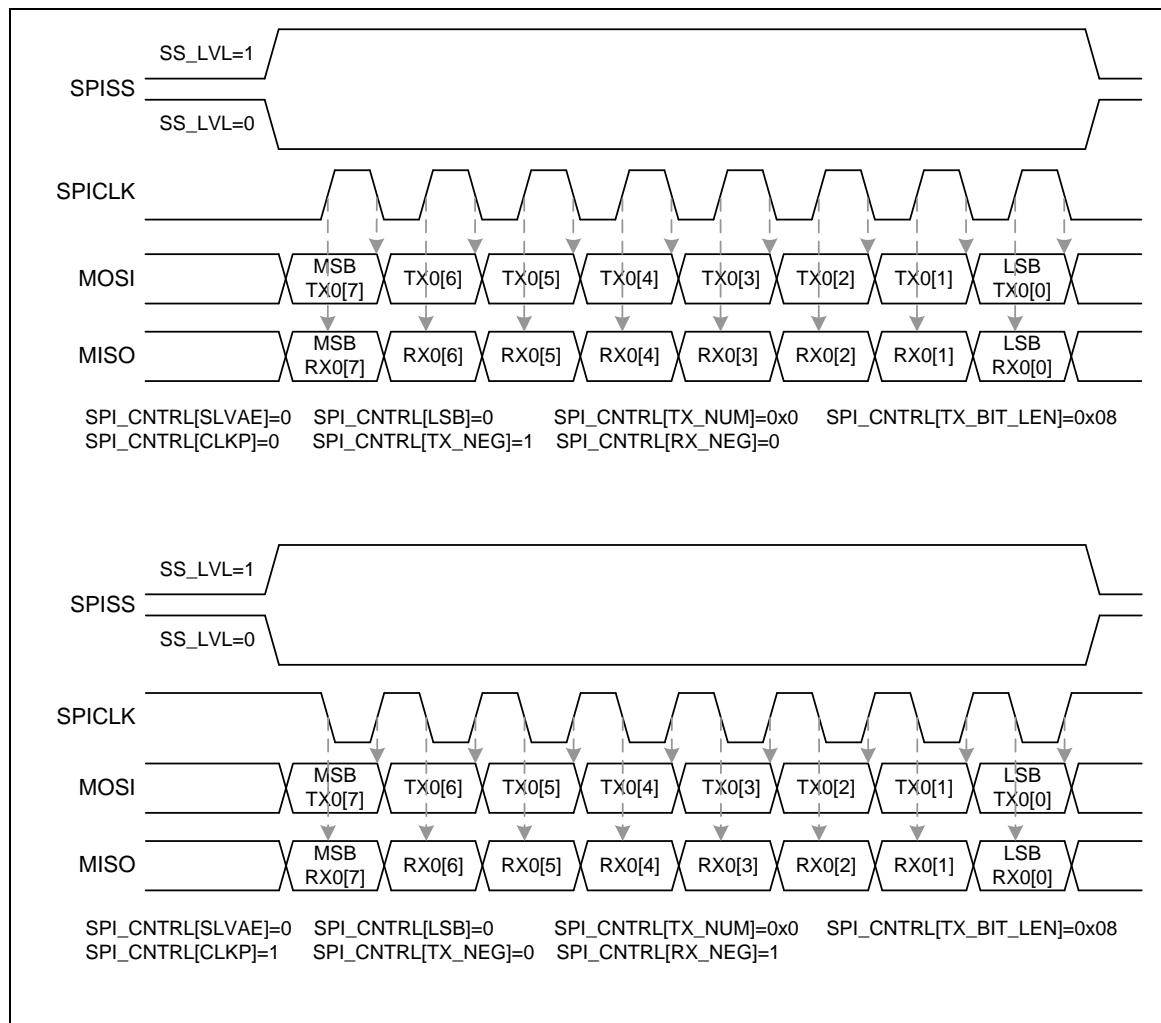

Figure 6-96 SPI Timing in Master Mode

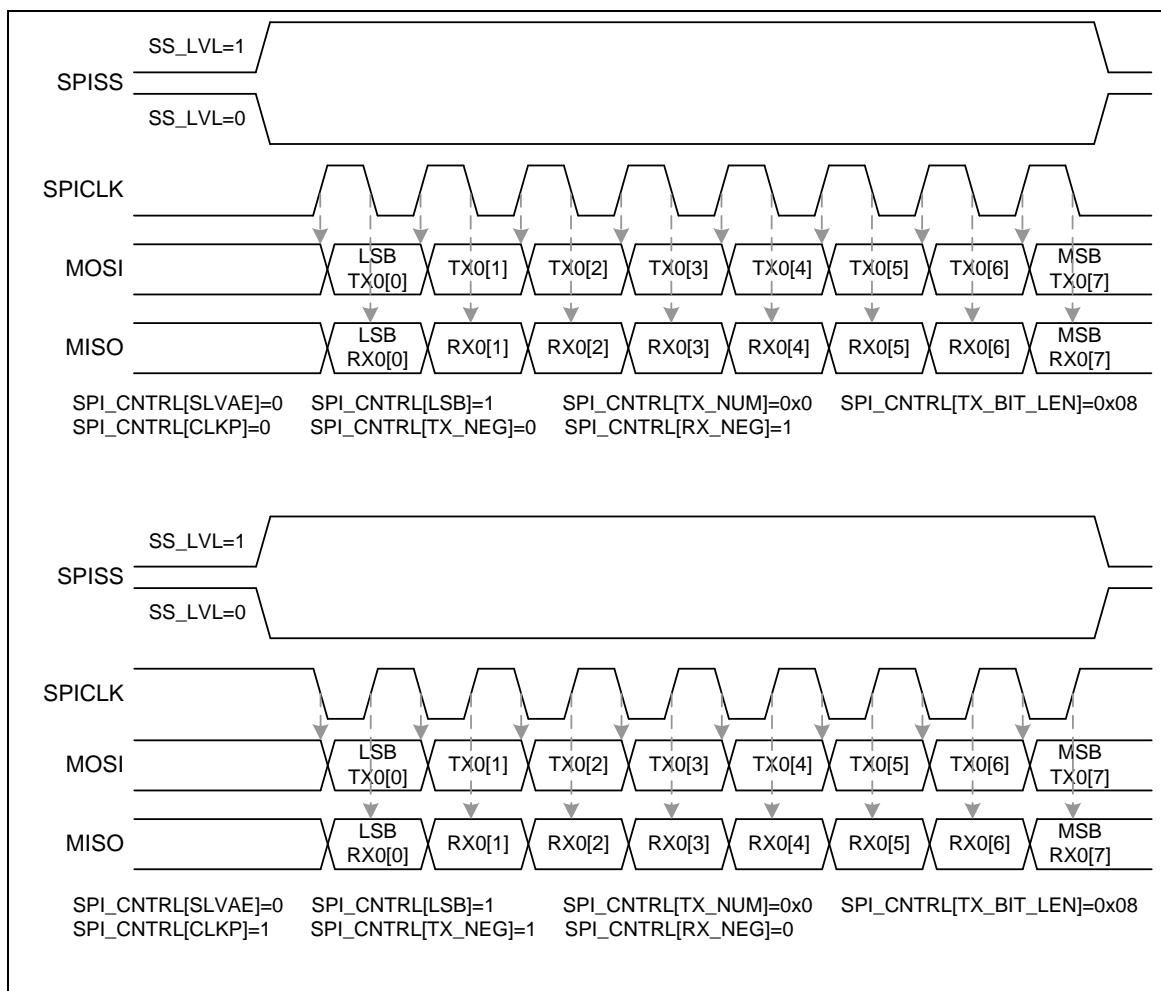

Figure 6-97 SPI Timing in Master Mode (Alternate Phase of SPICLK)

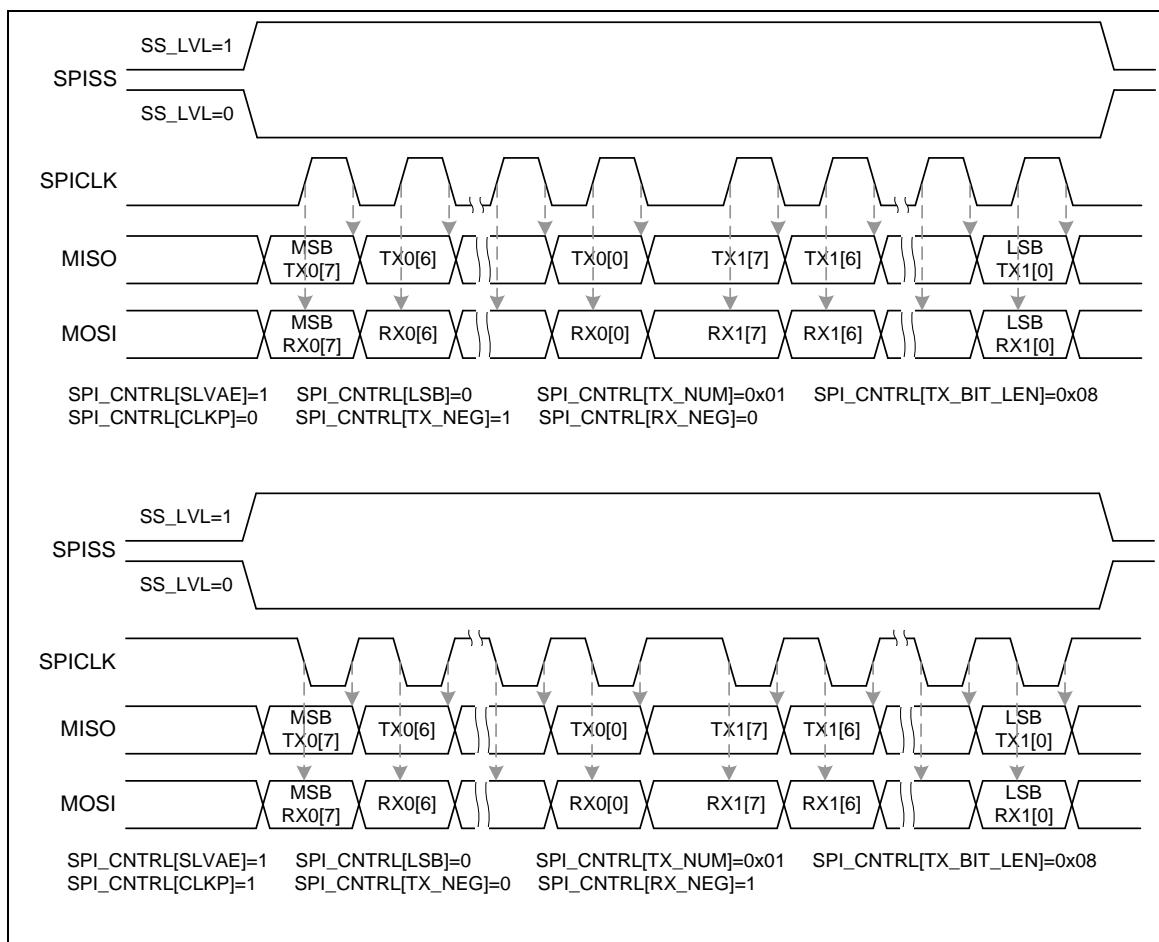

Figure 6-98 SPI Timing in Slave Mode

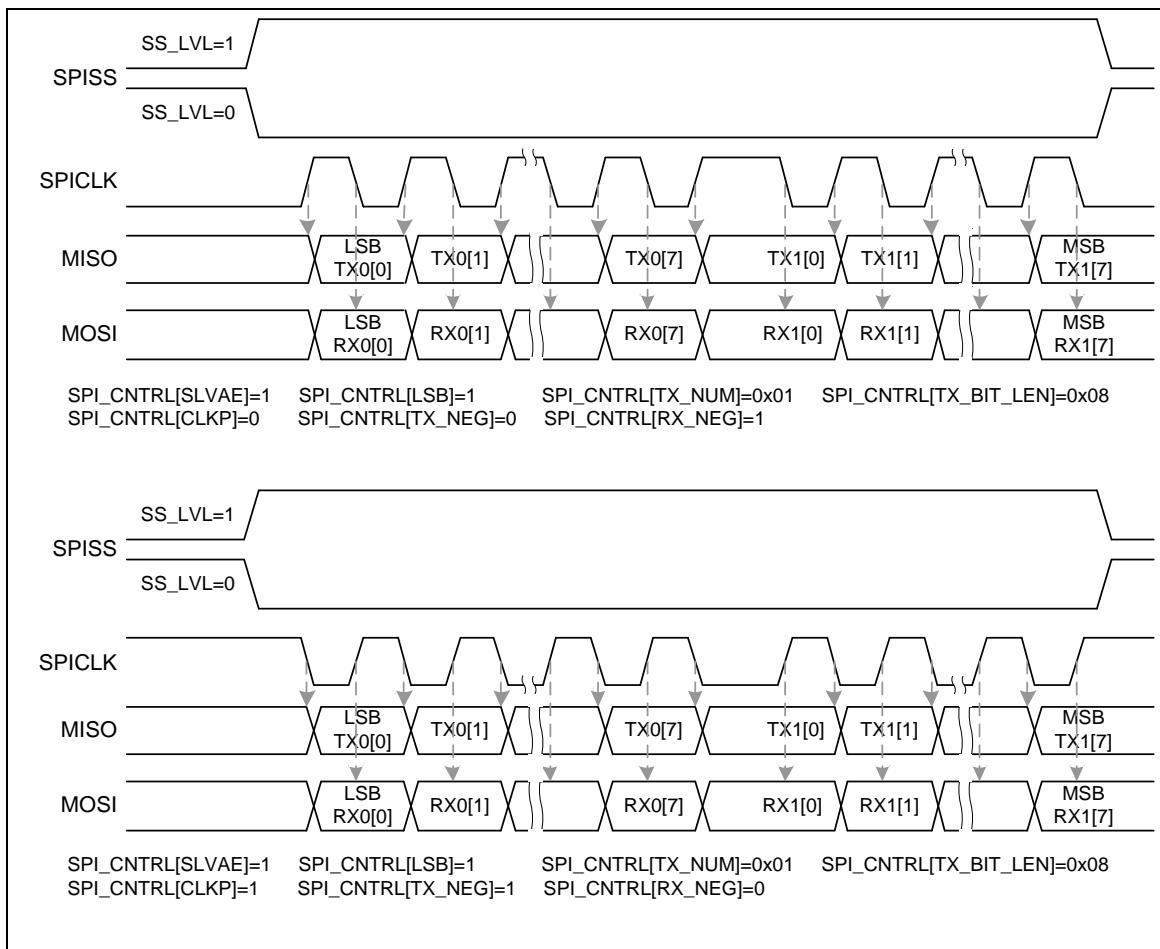

Figure 6-99 SPI Timing in Slave Mode (Alternate Phase of SPICLK)

6.13.7 Programming Examples

Example 1: SPI controller is set as a master to access an off-chip slave device with following specifications on M05xxDN/DE:

- Data bit is latched on positive edge of bus clock
- Data bit is driven on negative edge of bus clock
- Data is transferred from MSB first
- Data width is 8 bits
- SPICLK is idle at low state
- Only one byte of data to be transmitted/received in a transaction
- Connect with an off-chip slave device. Slave select signal is active low

The operation flow is described below.

- 1) Set the DIVIDER (SPI_DIVIDER[7:0]) to determine the output frequency of bus clock.
- 2) Write the related settings into the SPI_CNTRL register to control the SPI master actions.

1. Set this SPI controller as master device in SLAVE bit (SPI_CNTRL[18] = 0).
 2. Force the bus clock idle state at low in CLKP bit (SPI_CNTRL[11] = 0).
 3. Select data transmitted on negative edge of bus clock in TX_NEG bit (SPI_CNTRL[2] = 1).
 4. Select data latched on positive edge of bus clock in RX_NEG bit (SPI_CNTRL[1] = 0).
 5. Set the bit length of word transfer as 8-bit in TX_BIT_LEN bit field (SPI_CNTRL[7:3] = 0x08).
 6. Set MSB transfer first in MSB bit (SPI_CNTRL[10] = 0), and need not to care the SP_CYCLE bit field (SPI_CNTRL[15:12]) due to it is not in FIFO mode in this case.
- 3) Write the SPI_SSR register a proper value for the related settings of Master mode.
1. Clear the Automatic Slave Select bit AUTOSS(SPI_SSR[3] = 0).
Select low level trigger output of slave select signal in the Slave Select Active Level control bit, SS_LVL (SPI_SSR[2] = 0).
 2. Set the slave select signal to be active by setting the Slave Select control bit SSR (SPI_SSR[0]) to active the off-chip slave device.
- 4) If this SPI master attempts to transmit (write) one byte data to the off-chip slave device, write the byte data that will be transmitted into the SPI_TX0 register.
- 5) If this SPI master just only attempts to receive (read) one byte data from the off-chip slave device and does not care what data will be transmitted, the SPI_TX0 register does not need to be updated by software.
- 6) Set the GO_BUSY bit (SPI_CNTRL[0] = 1) to start the data transfer with the SPI interface.
- 7) Waiting for SPI interrupt (if the Interrupt Enable IE bit was set) or just polling the GO_BUSY bit till it is cleared to 0 by hardware automatically.
- 8) Read out the received one byte data from SPI_RX0[7:0].
- 9) Go to 4) to continue another data transfer or set SSR[0] bit to 0 to inactivate the off-chip slave device.

The following is a sample based on M051 series BSP for the SPI data transfer described above.

```
/* Set module clock divider. SPI clock rate = HCLK / ((11+1)*2) = 2MHz */
SPI0->DIVIDER = SPI0->DIVIDER & (~SPI_DIVIDER_DIVIDER_Msk) | SPI_DIVIDER_DIV(11);

/* Configure SPI0 as a master, MSB first, clock idle low, falling clock edge Tx, rising edge Rx and 8-bit transaction */
SPI0->CNTRL = SPI_CNTRL_MASTER_MODE | SPI_CNTRL_MSB_FIRST | SPI_CNTRL_CLK_IDLE_LOW |
               SPI_CNTRL_TX_FALLING | SPI_CNTRL_RX_RISING | SPI_CNTRL_TX_BIT_LEN(8);

/* Disable the automatic hardware slave select function. Select the SS pin and configure as low-active. */
SPI0->SSR = SPI_SSR_SW_SS_PIN_LOW;

/* write the first data of source buffer to Tx register of SPI0. */
_SPI_WRITE_TX_BUFFER0(SPI0, SourceData[0]);

/* Start the data transfer */
_SPI_SET_GO(SPI0);

/* Check the GO_BUSY bit */
While(SPI0->CNTRL & SPI_CNTRL_GO_BUSY);

/* Read the received data */
DestData[0] = _SPI_GET_RX0_DATA(SPI0)&0xFF;
...
```

Example 2: The SPI controller is set as a slave device and connects with an off-chip master device. The off-chip master device communicates with the on-chip SPI slave controller through the SPI interface with the following specifications on M05xxDN/DE:

- Data bit is latched on positive edge of bus clock
- Data bit is driven on negative edge of bus clock
- Data is transferred from LSB first
- Data width is 8 bits
- SPICLK is idle at high state
- Only one byte of data to be transmitted/received in a transaction
- Slave select signal is high level trigger

The operation flow is described below.

- 1) Set the DIVIDER (SPI_DIVIDER[7:0]) to determine the slave peripheral clock frequency. The slave peripheral clock frequency must be larger than the SPI bus clock frequency.
- 2) Write the SPI_SSR register a proper value for the related settings of Slave mode. Select high level and level trigger for the input of slave select signal by setting the Slave Select Active Level control bit SS_LVL (SPI_SSR[2] = 1) and the Slave Select Level Trigger bit SS_LTRIG (SPI_SSR[4] = 1).
- 3) Write the related settings into the SPI_CNTRL register to control this SPI slave actions.
 1. Set this SPI controller as slave device in SLAVE bit (SPI_CNTRL[18] = 1).
 2. Select the bus clock idle state at high in CLKP bit (SPI_CNTRL[11] = 1).
 3. Select data transmitted on negative edge of bus clock in TX_NEG bit (SPI_CNTRL[2] = 1).
 4. Select data latched on positive edge of bus clock in RX_NEG bit (SPI_CNTRL[1] = 0).
 5. Set the bit length of word transfer as 8-bit in TX_BIT_LEN bit field (SPI_CNTRL[7:3] = 0x08).
 6. Set only one time of word transfer in TX_NUM (SPI_CNTRL[9:8] = 0x0).
 7. Set LSB transfer first in LSB bit (SPI_CNTRL[10] = 1), and need not to care the SP_CYCLE bit field (SPI_CNTRL[15:12]) due to it is not burst mode in this case.
- 4) If this SPI slave attempts to transmit (be read) one byte data to the off-chip master device, write the byte data that will be transmitted into the SPI_TX0 register.
- 5) If this SPI slave just only attempts to receive (be written) one byte data from the off-chip master device and does not care what data will be transmitted, the SPI_TX0 register does not need to be updated by software.
- 6) Set the GO_BUSY bit (SPI_CNTRL[0] = 1) to wait for the slave select trigger input and bus clock input from the off-chip master device to start the data transfer with the SPI interface.
- 7) Waiting for SPI interrupt (if the Interrupt Enable IE bit was set), or just polling the GO_BUSY bit till it is cleared to 0 by hardware automatically.
- 8) Read out the received one byte data from SPI_RX0[7:0].
- 9) Go to 4) to continue another data transfer or clear the GO_BUSY bit to stop data transfer.

The following is a sample based on M051 series BSP for the SPI data transfer described above.

```
/* Configure SPI0 as a high level active device. */
SPI0->SSR = SPI_SSR_SLAVE_HIGH_LEVEL_ACTIVE;

/* Configure SPI0 as a slave, LSB first, clock idle high, falling clock edge Tx, rising edge Rx and 8-bit transaction */
SPI0->CNTRL = SPI_CNTRL_SLAVE_MODE | SPI_CNTRL_LSB_FIRST | SPI_CNTRL_CLK_IDLE_HIGH
               SPI_CNTRL_TX_FALLING | SPI_CNTRL_RX_RISING | SPI_CNTRL_TX_BIT_LEN(8);
/* write the first data of source buffer to Tx register of SPI0. */
_SPI_WRITE_TX_BUFFER0(SPI0, SourceData[0]);
/* set the GO_BUSY bit of SPI0 */
_SPI_SET_GO(SPI0);
/* Check the GO_BUSY bit */
While(SPI0->CNTRL & SPI_CNTRL_GO_BUSY);
/* Read the received data */
DestData[0] = _SPI_GET_RX0_DATA(SPI0)&0xFF;
...
```

TX_BIT_LEN					TX_NEG	RX_NEG	GO_BUSY

Bits	Description	
[31:28]	Reserved	Reserved.
[27]	TX_FULL	Transmit FIFO Buffer Full Indicator (Read Only) (M05xxDN/DE Only) It is a mutual mirror bit of SPI_STATUS[27]. 0 = Indicates that the transmit FIFO buffer is not full. 1 = Indicates that the transmit FIFO buffer is full.
[26]	TX_EMPTY	Transmit FIFO Buffer Empty Indicator (Read Only) (M05xxDN/DE Only) It is a mutual mirror bit of SPI_STATUS[26]. 0 = Indicates that the transmit FIFO buffer is not empty. 1 = Indicates that the transmit FIFO buffer is empty.
[25]	RX_FULL	Receive FIFO Buffer Full Indicator (Read Only) (M05xxDN/DE Only) It is a mutual mirror bit of SPI_STATUS[25]. 0 = Indicates that the receive FIFO buffer is not full. 1 = Indicates that the receive FIFO buffer is full.

[24]	RX_EMPTY	Receive FIFO Buffer Empty Indicator (Read Only) (M05xxDN/DE Only) It is a mutual mirror bit of SPI_CNTRL[24]. 0 = Indicates that the receive FIFO buffer is not empty. 1 = Indicates that the receive FIFO buffer is empty.
[23]	VARCLK_EN	Variable Clock Enable Control (M05xxBN Master Mode Only) 0 = The bus clock output frequency is fixed and decided only by the value of DIVIDER. 1 = The bus clock output frequency is variable. The output frequency is decided by the value of VARCLK, DIVIDER, and DIVIDER2. Note: When this VARCLK_EN bit is set, the setting of TX_BIT_LEN must be programmed as 0x10 (16-bit mode).
[22]	Reserved	Reserved.
[21]	FIFO	FIFO Mode Enable Control (M05xxDN/DE Only) In Master mode, if the FIFO mode is enabled, the GO_BUSY bit will be set to 1 automatically after writing data into the 8-depth transmit FIFO. When all data stored at transmit FIFO buffer are transferred, the GO_BUSY bit will back to 0. 0 = FIFO Mode Disabled. 1 = FIFO Mode Enabled. Note 1: Before enabling FIFO mode, the other related settings should be set in advance. Note 2: On M05xxBN, this bit must be 0.
[20:19]	REORDER	Byte Reorder Function and Byte Suspend Function Selection On M05xxBN: 00 = Disable both byte reorder and byte suspend functions. 01 = Enable byte reorder function and insert a byte suspend interval (2~17 SPICLK cycles) among each byte. The setting of TX_BIT_LEN must be configured as 0x00 (32 bits). 10 = Enable byte reorder function, but disable byte suspend function. 11 = Disable byte reorder function, but insert a suspend interval (2~17 SPICLK cycles) among each byte. The setting of TX_BIT_LEN must be configured as 0x00 (32 bits). Note 1: The byte reorder function is only available if TX_BIT_LEN is defined as 16, 24, and 32 bits. Note 2: In Slave mode with level-trigger configuration, if the byte suspend function is enabled, the slave select pin must be kept at active state during the successive four bytes transfer. On M05xxDN/DE: 00 = Byte reorder function and byte suspend function are Disabled. 01 = Byte reorder function Enabled. Byte suspend interval is determined by the setting of SP_CYCLE. Set SP_CYCLE to 0 to disabled byte suspend function. 10 = Reserved. 11 = Reserved. Note: Byte reorder function is only available if TX_BIT_LEN is defined as 16, 24, and 32 bits.
[18]	SLAVE	Slave Mode Control 0 = Master mode. 1 = Slave mode.
[17]	IE	Unit-transfer Interrupt Enable Control 0 = SPI unit-transfer interrupt Disabled. 1 = SPI unit-transfer interrupt Enabled.
[16]	IF	Unit-transfer Interrupt Flag 0 = No transaction has been finished since this bit was cleared to 0. 1 = SPI controller has finished one unit transfer.

		Note: This bit will be cleared by writing 1 to itself.
[15:12]	SP_CYCLE	<p>Suspend Interval (Master Only)</p> <p>These four bits provide configurable suspend interval between two successive transactions in a transfer. The definition of the suspend interval is the interval between the last clock edge of the preceding transaction word and the first clock edge of the following transaction word.</p> <p>On M05xxBN:</p> <p>The default value is 0x0. When TX_NUM = 00b and REORDER = 00b/10b, setting this field has no effect on transfer. The desired suspend interval is obtained according to the following equation:</p> <p>For byte suspend interval and burst mode suspend interval: $(SP_CYCLE[3:0] + 2) * \text{period of SPICLK} + 1 \text{ system clock cycle}$</p> <p>Example: $SP_CYCLE = 0x0 \dots 2 \text{ SPICLK clock cycle} + 1 \text{ system clock cycle.}$ $SP_CYCLE = 0x1 \dots 3 \text{ SPICLK clock cycle} + 1 \text{ system clock cycle.}$ $SP_CYCLE = 0xE \dots 16 \text{ SPICLK clock cycle} + 1 \text{ system clock cycle.}$ $SP_CYCLE = 0xF \dots 17 \text{ SPICLK clock cycle} + 1 \text{ system clock cycle.}$</p> <p>If the SPI bus clock rate equals system clock rate, that is to say, the DIV_ONE feature is enabled, the burst mode suspend interval period is $(SP_CYCLE[3:0] * 2 + 3.5) * \text{period of system clock}$</p> <p>On M05xxDN/DE:</p> <p>The default value is 0x3. The period of the suspend interval is obtained according to the following equation: $(SP_CYCLE[3:0] + 0.5) * \text{period of SPICLK clock cycle}$</p> <p>Example: $SP_CYCLE = 0x0 \dots 0.5 \text{ SPICLK clock cycle.}$ $SP_CYCLE = 0x1 \dots 1.5 \text{ SPICLK clock cycle.}$ $SP_CYCLE = 0xE \dots 14.5 \text{ SPICLK clock cycle.}$ $SP_CYCLE = 0xF \dots 15.5 \text{ SPICLK clock cycle.}$</p>
[11]	CLKP	Clock Polarity 0 = SPICLK idle low. 1 = SPICLK idle high.
[10]	LSB	LSB First 0 = The MSB is transmitted/received first. 1 = The LSB is transmitted/received first.
[9:8]	TX_NUM	<p>Numbers of Transmit/Receive Word (M05xxBN Only)</p> <p>This field specifies how many transmit/receive word numbers should be executed in one transfer.</p> <p>00 = Burst mode Disabled. Only one word will be transferred when the GO_BUSY bit is set to 1.</p> <p>01 = Burst mode Enabled. Two successive words will be transferred when the GO_BUSY bit is set to 1.</p> <p>10 = Reserved.</p> <p>11 = Reserved.</p> <p>Note: In Slave mode with level-trigger configuration, if TX_NUM is set to 01, the slave select pin must be kept at active state during the successive data transfer.</p>
[7:3]	TX_BIT_LEN	Transfer Bit Length

		<p>This field specifies how many bits can be transmitted / received in one transaction. The minimum bit length is 8 bits and can up to 32 bits.</p> <p>TX_BIT_LEN = 0x08 ... 8 bit.</p> <p>TX_BIT_LEN = 0x09 ... 9 bits.</p> <p>.....</p> <p>TX_BIT_LEN = 0x1F ... 31 bits.</p> <p>TX_BIT_LEN = 0x00 ... 32 bits.</p>
[2]	TX_NEG	<p>Transmit on Negative Edge</p> <p>0 = The transmitted data output signal is driven on the rising edge of SPICLK. 1 = The transmitted data output signal is driven on the falling edge of SPICLK.</p>
[1]	RX_NEG	<p>Receive on Negative Edge</p> <p>0 = The received data input signal is latched on the rising edge of SPICLK. 1 = The received data input signal is latched on the falling edge of SPICLK.</p>
[0]	GO_BUSY	<p>SPI Transfer Trigger and Busy Status</p> <p>On M05xxBN:</p> <p>During the data transfer, this bit keeps the value of 1. As the transfer is finished, this bit will be cleared automatically.</p> <p>0 = Writing 0 to this bit to stop data transfer if SPI is transferring. 1 = In Master mode, writing 1 to this bit will start the SPI data transfer; in Slave mode, writing 1 to this bit indicates that the slave is ready to communicate with a master.</p> <p>Note: All registers should be set before writing 1 to the GO_BUSY bit.</p> <p>On M05xxDN/DE:</p> <p>In FIFO mode, this bit will be controlled by hardware. Software cannot modify this bit. If FIFO mode is disabled, during the data transfer, this bit keeps the value of 1. As the transfer is finished, this bit will be cleared automatically.</p> <p>0 = Writing 0 to this bit to stop data transfer if SPI is transferring. 1 = In Master mode, writing 1 to this bit to start the SPI data transfer; in Slave mode, writing 1 to this bit indicates that the slave is ready to communicate with a master.</p> <p>Note 1: When FIFO mode is disabled, all configurations should be ready before writing 1 to the GO_BUSY bit.</p> <p>Note 2: In M05xxDN/DE SPI Slave mode, if FIFO mode is disabled and the SPI bus clock is kept at idle state during a data transfer, the GO_BUSY bit will not be cleared to 0 when slave select signal goes to inactive state.</p>

SPI Divider Register (SPI_DIVIDER)

Register	Offset	R/W	Description				Reset Value
SPI_DIVIDER	SPIx_BA+0x04	R/W	Clock Divider Register				0x0000_0000

31	30	29	28	27	26	25	24
DIVIDER2							
23	22	21	20	19	18	17	16
DIVIDER2							
15	14	13	12	11	10	9	8
DIVIDER							
7	6	5	4	3	2	1	0
DIVIDER							

Bits	Description
[31:16]	<p>Clock Divider 2 (M05xxBN Master Mode Only)</p> <p>The value in this field is the 2nd frequency divider for generating the bus clock on the output SPICLK. The desired frequency is obtained according to the following equation:</p> $f_{sclk} = \frac{f_{pclk}}{(DIVIDER2 + 1) * 2}$ <p>If VARCLK_EN is cleared to 0, this setting is unmeaning.</p>
[15:0]	<p>Clock Divider</p> <p>On M05xxBN:</p> <p>Only available in Master mode. The value in this field is the frequency divider to determine the master's peripheral clock frequency and the bus clock frequency on the SPICLK output pin. The desired frequency is obtained according to the following equation:</p> $f_{sclk} = \frac{f_{pclk}}{(DIVIDER + 1) * 2}$ <p>In Slave mode, the period of SPI bus clock driven by a master shall equal or over 5 times the period of PCLK. In other words, the maximum frequency of SPI bus clock is the fifth of the frequency of slave's PCLK.</p> <p>On M05xxDN/DE:</p> <p>Only DIVIDER[7:0] is available. The value in this field is the frequency divider to determine the SPI peripheral clock frequency, f_{spi}, and the SPI master's bus clock frequency on the SPICLK output pin. The frequency is obtained according to the following equation.</p> <p>If the bit of BCn, SPI_CNTRL2[31], is set to 0,</p> $f_{spi} = \frac{f_{SPI_clock_src}}{(DIVIDER + 1) * 2}$ <p>else if BCn is set to 1,</p> $f_{spi} = \frac{f_{SPI_clock_src}}{(DIVIDER + 1)}$

where

$f_{SPI_clock_src}$ is the SPI peripheral clock source which is defined in the CLKSEL1 register.

SPI Slave Select Register (SPI_SSR)

Register	Offset	R/W	Description				Reset Value
SPI_SSR	SPIx_BA+0x08	R/W	Slave Select Register				0x0000_0000

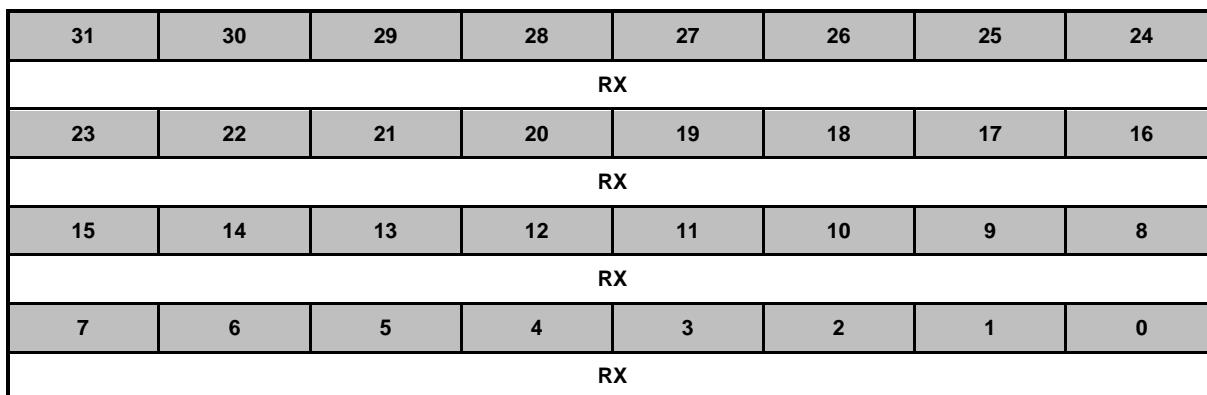

31	30	29	28	27	26	25	24
Reserved							
23	22	21	20	19	18	17	16
Reserved							
15	14	13	12	11	10	9	8
Reserved							
7	6	5	4	3	2	1	0
Reserved		LTRIG_FLAG	SS_LTRIG	AUTOSS	SS_LVL	Reserved	SSR

Bits	Description	
[31:6]	Reserved	Reserved.
[5]	LTRIG_FLAG	<p>Level Trigger Flag When the SS_LTRIG bit is set in Slave mode, this bit can be read to indicate the received bit number is met the requirement or not. 0 = The transaction number or the transferred bit length of one transaction does not meet the specified requirements. 1 = The transaction number and the transferred bit length met the specified requirements which defined in TX_NUM and TX_BIT_LEN. The TX_NUM setting is not available on M05xxDN/DE, only the setting of TX_BIT_LEN will be considered. Note: This bit is READ only and only available in Slave mode.</p>
[4]	SS_LTRIG	<p>Slave Select Level Trigger Enable (Slave Only) 0 = The input slave select signal is edge-trigger. This is the default value. It depends on SS_LVL to decide the signal is active at falling-edge or rising-edge. 1 = The slave select signal will be level-trigger. It depends on SS_LVL to decide the signal is active low or active high.</p>
[3]	AUTOSS	<p>Automatic Slave Select Function Enable (Master Only) 0 = If this bit is cleared, slave select signal will be asserted/de-asserted by setting /clearing SSR bit. 1 = If this bit is set, SPISSx signal will be generated automatically, which means that slave select signal will be asserted by the SPI controller when transmit/receive is started by setting GO_BUSY, and will be de-asserted after each transmit/receive is finished.</p>
[2]	SS_LVL	<p>Slave Select Active Level This bit defines the active status of slave select signal (SPISSx). 0 = The slave select signal SPISSx is active at low-level/falling-edge. 1 = The slave select signal SPISSx is active at high-level/rising-edge.</p>
[1]	Reserved	Reserved.
[0]	SSR	<p>Slave Select Control (Master Only) If AUTOSS bit is cleared to 0, 0 = Set the SPISSx line to inactive state.</p>

		<p>1 = Set the proper SPISSx line to active state. If AUTOSS bit is set to 1, 0 = Keep the SPISSx line at inactive state. 1 = Select the SPISSx line to be automatically driven to active state for the duration of transmission/reception, and will be driven to inactive state for the rest of the time. The active state of SPISSx is specified in SS_LVL bit.</p>
--	--	---

SPI Data Receive Register (SPI_RX)

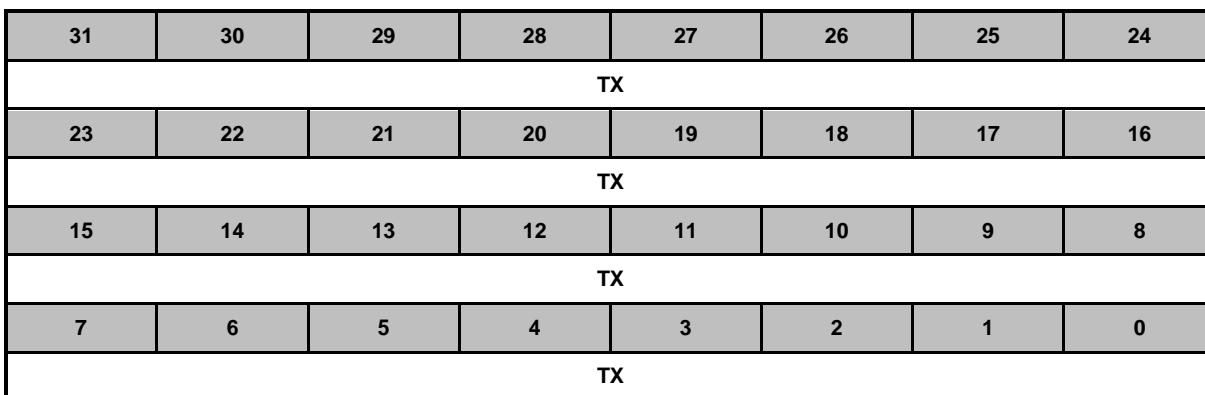

Register	Offset	R/W	Description				Reset Value
SPI_RX0	SPIx_BA+0x10	R	Data Receive Register 0				0x0000_0000
SPI_RX1	SPIx_BA+0x14	R	Data Receive Register 1 (M05xxBN Only)				0x0000_0000

Bits	Description								
[31:0]	RX	Data Receive Register The Data Receive Registers hold the value of received data of the last executed transfer. Valid bits depend on the transmit bit length field in the SPI_CNTRL register. For example, if TX_BIT_LEN is set to 0x08 and TX_NUM is set to 0x0, bit RX0[7:0] holds the received data. The values of the other bits are unknown. The Data Receive Registers are read-only registers.							

SPI Data Transmit Register (SPI_TX)

Register	Offset	R/W	Description	Reset Value
SPI_TX0	SPIx_BA+0x20	W	Data Transmit Register 0	0x0000_0000
SPI_TX1	SPIx_BA+0x24	W	Data Transmit Register 1 (M05xxBN Only)	0x0000_0000

Bits	Description	
[31:0]	TX	<p>Data Transmit Register</p> <p>The Data Transmit Registers hold the data to be transmitted in the next transfer. Valid bits depend on the transmit bit length field in the CNTRL register.</p> <p>For example, if TX_BIT_LEN is set to 0x08 and the TX_NUM is set to 0x0, the bit TX0[7:0] will be transmitted in next transfer. If TX_BIT_LEN is set to 0x00 and TX_NUM is set to 0x1, the SPI controller will perform two 32-bit transmit/receive successive using the same setting. The transmission sequence is TX0[31:0] first and then TX1[31:0].</p>

SPI Variable Clock Pattern Register (SPI_VARCLK)

Register	Offset	R/W	Description					Reset Value
SPI_VARCLK	SPIx_BA+0x34	R/W	Variable Clock Pattern Register (M05xxBN Only)					0x007F_FF87

31	30	29	28	27	26	25	24
VARCLK

VARCLK							
15	14	13	12	11	10	9	8
VARCLK							
7	6	5	4	3	2	1	0
VARCLK							

Bits	Description	
[31:0]	VARCLK	<p>Variable Clock Pattern</p> <p>The value in this field is the frequency patterns of the SPI bus clock. If the bit pattern of VARCLK is '0', the output frequency of SPICLK is according the value of DIVIDER. If the bit patterns of VARCLK are '1', the output frequency of SPICLK is according the value of DIVIDER2. Refer to the SPI_DIVIDER register.</p> <p>Note: Refer to the Variable Bus Clock Frequency paragraph for more detailed description.</p>

SPI Control and Status Register 2 (SPI_CNTRL2)

Register	Offset	R/W	Description				Reset Value
SPI_CNTRL2	SPIx_BA+0x3C	R/W	Control and Status Register 2				0x0000_0000

On M05xxBN:

31	30	29	28	27	26	25	24
Reserved							
23	22	21	20	19	18	17	16
Reserved							
15	14	13	12	11	10	9	8
Reserved				SLV_START_INTSTS	SSTA_INTEN	SLV_ABORT	NOSLVSEL
7	6	5	4	3	2	1	0
Reserved							DIV_ONE

On M05xxDN/DE:

31	30	29	28	27	26	25	24
BCn	Reserved						
23	22	21	20	19	18	17	16
Reserved							SS_INT_OPT
15	14	13	12	11	10	9	8
Reserved				SLV_START_INTSTS	SSTA_INTEN	SLV_ABORT	NOSLVSEL
7	6	5	4	3	2	1	0
Reserved							

Bits	Description	
[31]	BCn	Clock Configuration Backward Compatible Option (M05xxDN/DE Only) 0 = The clock configuration is backward compatible to M05xxBN. 1 = The clock configuration is not backward compatible to M05xxBN. Refer to the description of SPI_DIVIDER register for details.
[30:17]	Reserved	Reserved.
[16]	SS_INT_OPT	Slave Select Inactive Interrupt Option (M05xxDN/DE Only) This setting is only available if the SPI controller is configured as level trigger slave device. 0 = As the slave select signal goes to inactive level, the IF bit will NOT be set to 1. 1 = As the slave select signal goes to inactive level, the IF bit will be set to 1.
[15:12]	Reserved	Reserved.
[11]	SLV_START_INTSTS	Slave 3-wire Mode Start Interrupt Status This bit dedicates if a transaction has started in Slave 3-wire mode. It is a mutual mirror bit of SPI_STATUS[11].

		0 = Slave does not detect any SPI bus clock transition since the SSTA_INTEN bit was set to 1. 1 = A transaction has started in Slave 3-wire mode. It will be cleared automatically when a transaction is done or by writing 1 to this bit.
[10]	SSTA_INTEN	Slave 3-wire Mode Start Interrupt Enable It is used to enable interrupt when the transfer has started in Slave 3-wire mode. If there is no transfer done interrupt over the time period which is defined by user after the transfer start, user can set the SLV_ABORT bit to force the transfer done. 0 = Transaction start interrupt Disabled. 1 = Transaction start interrupt Enabled. It will be cleared to 0 as the current transfer is done or the SLV_START_INTSTS bit is cleared to 0.
[9]	SLV_ABORT	Slave 3-wire Mode Abort Control In normal operation, there is an interrupt event when the number of received bits meets the requirement which defined in TX_BIT_LEN and TX_NUM. The TX_NUM setting is not available on M05xxDN/DE, and only the setting of TX_BIT_LEN will be considered. If the number of received bits is less than the requirement and there is no more bus clock input over one transfer time in Slave 3-wire mode, user can set this bit to force the current transfer done and then user can get a unit transfer interrupt event. Note: This bit will be cleared to 0 automatically by hardware after it is set to 1 by software.
[8]	NOSLVSEL	Slave 3-wire Mode Enable This is used to ignore the slave select signal in Slave mode. The SPI controller can work with 3-wire interface including SPICLK, SPI_MISO, and SPI_MOSI when this bit is set to 1. 0 = The controller is 4-wire bi-direction interface. 1 = The controller is 3-wire bi-direction interface in Slave mode. When this bit is set to 1, the controller will be ready to transmit/receive data after the GO_BUSY bit is set to 1. Note: In Slave 3-wire mode, the SS_LTRIG bit (SPI_SSR[4]) shall be set as 1.
[7:1]	Reserved	Reserved.
[0]	DIV_ONE	SPI Bus Clock Divider Control (M05xxBN Master Mode Only) 0 = The SPI bus clock rate is determined by the setting of SPI_DIVIDER register. 1 = Enable the DIV_ONE feature. The SPI bus clock rate equals the system clock rate. Note: When this bit is set to 1, both the REORDER field and the VARCLK_EN field must be configured as 0. In other words, the byte-reorder function, byte suspend function and variable clock function must be disabled.

SPI FIFO Control Register (SPI_FIFO_CTL)

Register	Offset	R/W	Description				Reset Value

Bits	Description	
[31:30]	Reserved	Reserved.
[29:28]	TX_THRESHOLD	Transmit FIFO Threshold If the valid data count of the transmit FIFO buffer is less than or equal to the TX_THRESHOLD setting, the TX_INTSTS bit will be set to 1, else the TX_INTSTS bit will be cleared to 0.
[27:26]	Reserved	Reserved.
[25:24]	RX_THRESHOLD	Received FIFO Threshold If the valid data count of the receive FIFO buffer is larger than the RX_THRESHOLD setting, the RX_INTSTS bit will be set to 1, else the RX_INTSTS bit will be cleared to 0.
[23:22]	Reserved	Reserved.
[21]	TIMEOUT_INTEN	Receive FIFO Time-out Interrupt Enable Control 0 = Time-out interrupt Disabled. 1 = Time-out interrupt Enabled.
[20:7]	Reserved	Reserved.
[6]	RXOV_INTEN	Receive FIFO Overrun Interrupt Enable Control 0 = Receive FIFO overrun interrupt Disabled. 1 = Receive FIFO overrun interrupt Enabled.
[5:4]	Reserved	Reserved.
[3]	TX_INTEN	Transmit Threshold Interrupt Enable Control 0 = Transmit threshold interrupt Disabled. 1 = Transmit threshold interrupt Enabled.
[2]	RX_INTEN	Receive Threshold Interrupt Enable Control 0 = Receive threshold interrupt Disabled. 1 = Receive threshold interrupt Enabled.

[1]	TX_CLR	Clear Transmit FIFO Buffer 0 = No effect. 1 = Clear transmit FIFO buffer. The TX_FULL flag will be cleared to 0 and the TX_EMPTY flag will be set to 1. This bit will be cleared to 0 by hardware after software sets it to 1 and the transmit FIFO is cleared.
[0]	RX_CLR	Clear Receive FIFO Buffer 0 = No effect. 1 = Clear receive FIFO buffer. The RX_FULL flag will be cleared to 0 and the RX_EMPTY flag will be set to 1. This bit will be cleared to 0 by hardware after software sets it to 1 and the receive FIFO is cleared.

SPI Status Register (SPI_STATUS)

Bits	Description	
[31:28]	TX_FIFO_COUNT	Transmit FIFO Data Count (Read Only) Indicates the valid data count of transmit FIFO buffer.
[27]	TX_FULL	Transmit FIFO Buffer Full Indicator (Read Only) It is a mutual mirror bit of SPI_CNTRL[27]. 0 = The transmit FIFO buffer is not full. 1 = The transmit FIFO buffer is full.
[26]	TX_EMPTY	Transmit FIFO Buffer Empty Indicator (Read Only) It is a mutual mirror bit of SPI_CNTRL[26]. 0 = The transmit FIFO buffer is not empty. 1 = The transmit FIFO buffer is empty.
[25]	RX_FULL	Receive FIFO Buffer Full Indicator (Read Only) It is a mutual mirror bit of SPI_CNTRL[25]. 0 = The receive FIFO buffer is not full. 1 = The receive FIFO buffer is full.
[24]	RX_EMPTY	Receive FIFO Buffer Empty Indicator (Read Only) It is a mutual mirror bit of SPI_CNTRL[24]. 0 = The receive FIFO buffer is not empty. 1 = The receive FIFO buffer is empty.
[23:21]	Reserved	Reserved.
[20]	TIMEOUT	Time-out Interrupt Flag 0 = No receive FIFO time-out event. 1 = The receive FIFO buffer is not empty and it does not have been read over 64 SPI clock periods in Master mode or over 576 SPI peripheral clock periods in Slave mode. When the received FIFO buffer is read by software, the time-out status will be cleared automatically. Note: This bit will be cleared by writing 1 to itself.
[19:17]	Reserved	Reserved.

[16]	IF	SPI Unit-transfer Interrupt Flag It is a mutual mirror bit of SPI_CNTRL[16]. 0 = The transfer does not finish yet. 1 = The SPI controller has finished one unit transfer. Note: This bit will be cleared by writing 1 to itself.
[15:12]	RX_FIFO_COUNT	Receive FIFO Data Count (Read Only) Indicates the valid data count of receive FIFO buffer.
[11]	SLV_START_INTSTS	Slave Start Interrupt Status It is used to dedicate that the transfer has started in Slave 3-wire mode. It's a mutual mirror bit of SPI_CNTRL2[11]. 0 = The transfer is not started. 1 = The transfer has started in Slave 3-wire mode. It will be cleared as transfer done or by writing one to this bit.
[10:5]	Reserved	Reserved.
[4]	TX_INTSTS	Transmit FIFO Threshold Interrupt Status (Read Only) 0 = The valid data count within the transmit FIFO buffer is larger than the setting value of TX_THRESHOLD. 1 = The valid data count within the transmit FIFO buffer is less than or equal to the setting value of TX_THRESHOLD. Note: If TX_INEN = 1 and TX_INTSTS = 1, the SPI controller will generate a SPI interrupt request.
[3]	Reserved	Reserved.
[2]	RX_OVERRUN	Receive FIFO Overrun Status When the receive FIFO buffer is full, the follow-up data will be dropped and this bit will be set to 1. Note: This bit will be cleared by writing 1 to itself.
[1]	Reserved	Reserved.
[0]	RX_INTSTS	Receive FIFO Threshold Interrupt Status (Read Only) 0 = The valid data count within the Rx FIFO buffer is smaller than or equal to the setting value of RX_THRESHOLD. 1 = The valid data count within the receive FIFO buffer is larger than the setting value of RX_THRESHOLD. Note: If RX_INEN = 1 and RX_INTSTS = 1, the SPI controller will generate a SPI interrupt request.

6.14 Analog-to-Digital Converter (ADC)

6.14.1 Overview

The NuMicro® M05xxBN/DN/DE series contains one 12-bit successive approximation analog-to-digital converter (SAR A/D converter) with eight input channels. The A/D converter supports four operation modes: Single, Burst, Single-cycle Scan and Continuous Scan mode. The A/D converter can be started by software, external pin (STADC/P3.2) or PWM trigger (M05xxDN/DE only).

6.14.2 Features

- Analog input voltage range: $0 \sim AV_{DD}$.
- 12-bit resolution and 10-bit accuracy is guaranteed
- Up to eight single-end analog input channels or 4 differential analog input channels
- Maximum ADC peripheral clock frequency is 16 MHz
- Up to 760 kSPS sample rate
- Four operation modes:
 - ◆ Single mode: A/D conversion is performed one time on a specified channel.
 - ◆ Burst mode: A/D converter samples and converts the specified single channel and sequentially stores the result in FIFO.
 - ◆ Single-cycle Scan mode: A/D conversion is performed only one cycle on all specified channels with the sequence from the smallest numbered channel to the largest numbered channel.
 - ◆ Continuous Scan mode: A/D converter continuously performs Single-cycle Scan mode until software stops A/D conversion.
- An A/D conversion can be started by:
 - ◆ Software Write 1 to ADST bit
 - ◆ External pin (STADC)
 - ◆ PWM trigger with optional start delay period (M05xxDN/DE only)
- Each conversion result is held in data register of each channel with valid and overrun indicators.
- Conversion result can be compared with specified value and user can select whether to generate an interrupt when conversion result matches the compare register setting.
- Channel 7 supports 3 input sources: external analog voltage, internal band-gap voltage and
- Internal temperature sensor output.

6.14.3 Block Diagram

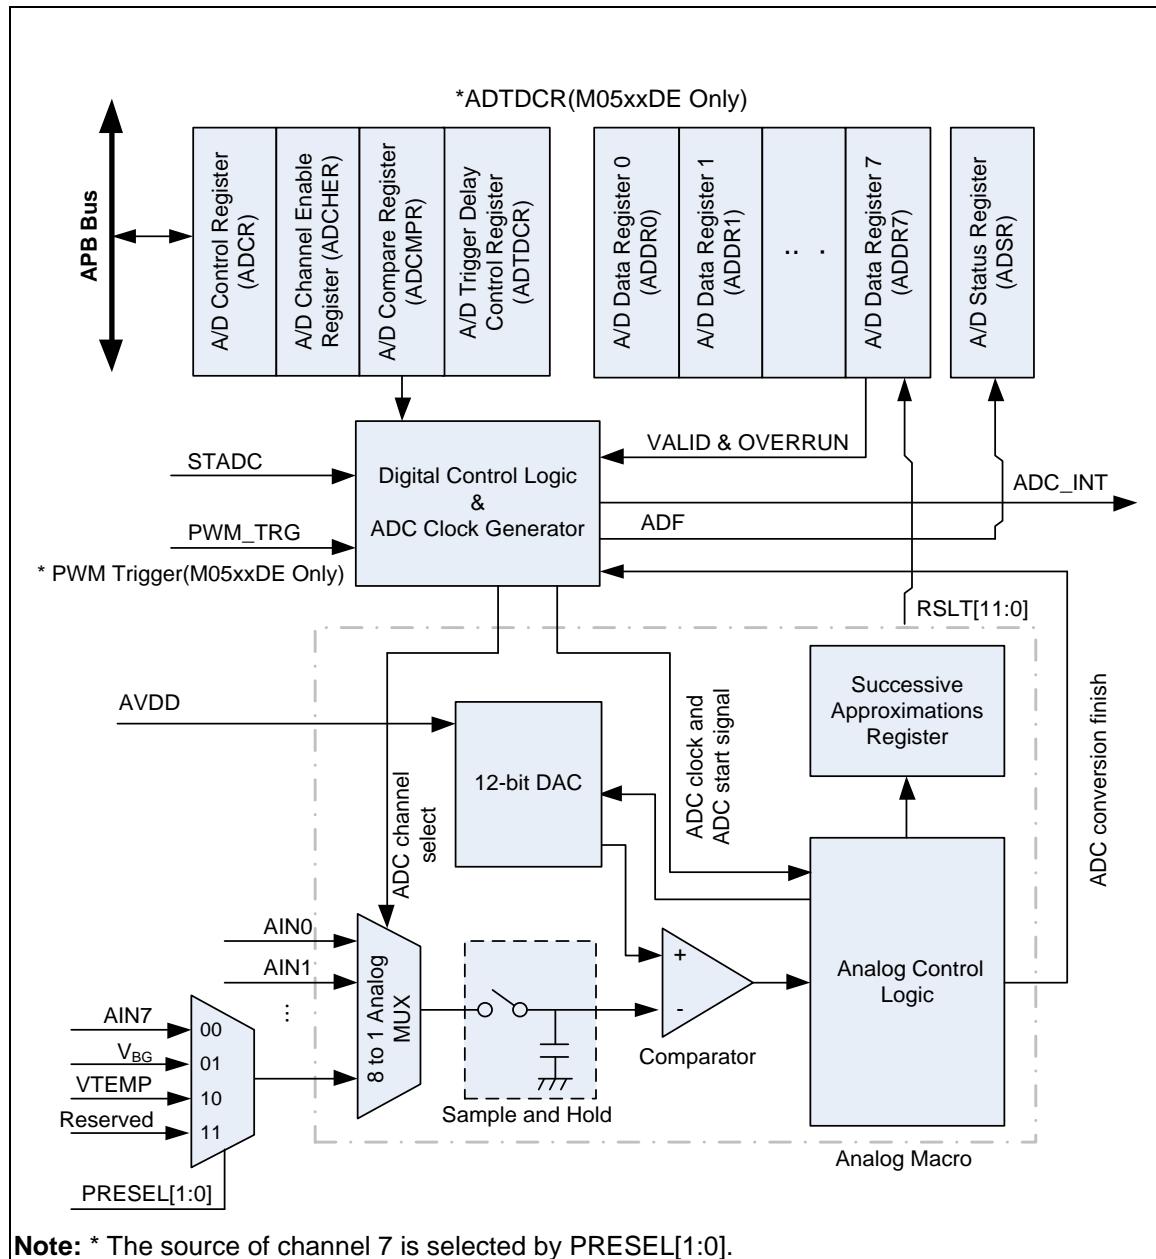

Figure 6-100 AD Controller Block Diagram

6.14.4 Basic Configuration

The ADC pin functions are configured in P1_MFP register. It is recommended to disable the digital input path of the analog input pins to avoid the leakage current. User can disable the digital input path by configuring P1_OFFD register.

The ADC peripheral clock can be enabled in APBCLK[28]. The ADC peripheral clock source is selected by CLKSEL1[3:2]. The clock prescalar is determined by CLKDIV[23:16].

6.14.5 Functional Description

The A/D converter operates by successive approximation with 12-bit resolution. The ADC has four operation modes: Single, Burst, Single-cycle Scan mode and Continuous Scan mode. When user wants to change the operation mode or analog input channel, in order to prevent incorrect operation, software must clear ADST bit to 0 in advance.

6.14.5.1 ADC peripheral Clock Generator

The maximum sampling rate is up to 760 kSPS. The ADC has four clock sources selected by ADC_S (CLKSEL1[3:2]), the ADC peripheral clock frequency is divided by an 8-bit pre-scalar with the following formula:

$\text{ADC peripheral clock frequency} = (\text{ADC peripheral clock source frequency}) / (\text{ADC_N} + 1)$; where the 8-bit ADC_N is located in register CLKDIV[23:16].

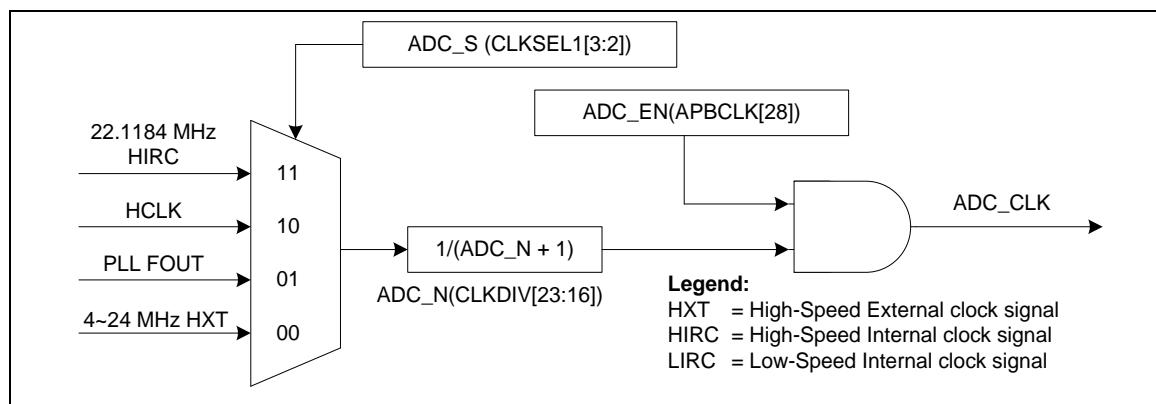

Figure 6-101 ADC Peripheral Clock Control

6.14.5.2 Single Mode

In Single mode, A/D conversion is performed only once on the specified single channel. The operations are as follows:

1. A/D conversion will be started when the ADST bit of ADCR is set to 1 by software or external trigger input.
2. When A/D conversion is finished, the result is stored in the A/D data register corresponding to the channel.
3. The ADF bit of ADSR register will be set to 1. If the ADIE bit of ADCR register is set to 1, the ADC interrupt will be asserted.
4. The ADST bit remains 1 during A/D conversion. When A/D conversion ends, the ADST bit is automatically cleared to 0 and the A/D converter enters idle state.

Note 1: If software enables more than one channel in Single mode, only the channel with the smallest number will be selected and the other enabled channels will be ignored.

Note 2: When hardware clears the ADST bit, the ADST bit must be kept at 0 at least one ADC peripheral clock period before setting it to 1 again, otherwise the A/D converter may not work (M05xxBN only).

Note 3: If ADST bit is cleared to 0 when ADC is in converting, the BUSY bit will be cleared to 0 immediately, ADC will finish the current conversion and save the result to the ADDR_x register of the enabled channel (M05xxBN only). But ADC cannot finish the current conversion and A/D converter enters idle state directly (M05xxDN/DE only).

Through the ADC Driver, user can call the flow below to operate Single mode.

```
/* Set the ADC operation mode as Single, input mode as single-end and enable the ADC converter */
ADC->ADCR = (ADC_ADCR_ADMD_SINGLE
               | ADC_ADCR_DIFFEN_SINGLE_END
               | ADC_ADCR_ADEN_CONVERTER_ENABLE);

/* Enable analog input channel 2 */
_ADC_SET_CHANNEL(1<<2);

/* Clear the A/D interrupt flag for safe */
ADC->ADSR = ADC_ADSR_ADF_Msk;

/* Enable the ADC interrupt */
_ADC_ENABLE_ADC_INT();
NVIC_EnableIRQ(ADC IRQn);

/* Start A/D conversion */
_ADC_START_CONVERT();
```

An example timing diagram for Single mode is shown below.

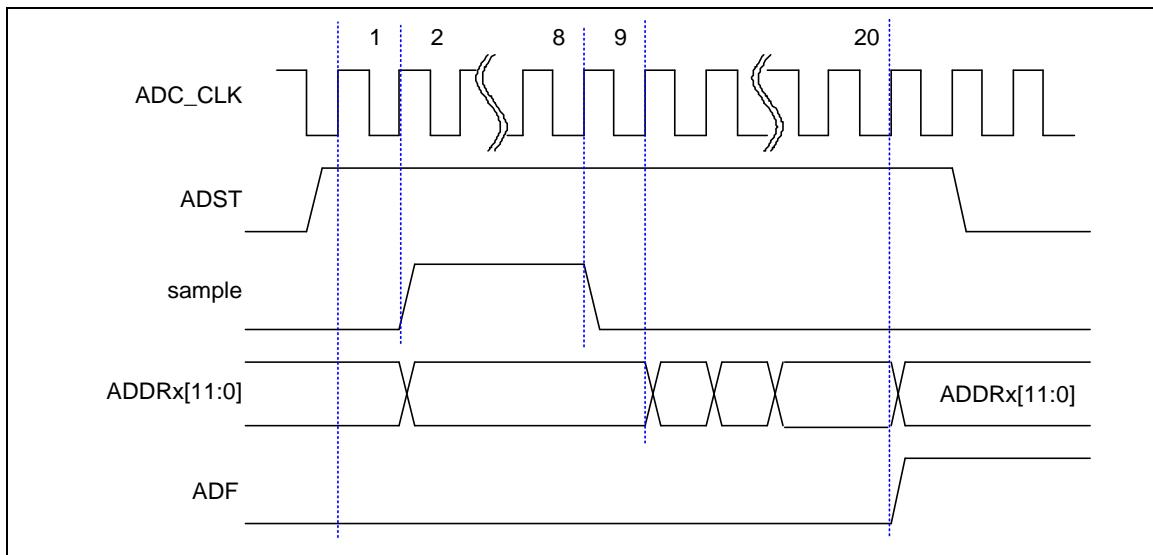

Figure 6-102 Single Mode Conversion Timing Diagram

6.14.5.3 Burst Mode

In Burst mode, A/D converter samples and converts the specified single channel and sequentially stores the result into FIFO (up to 8 samples). The operations are as follows:

1. When the ADST bit in ADCR is set to 1 by software or external trigger input, A/D conversion is started on the channel with the smallest number.
2. When A/D conversion for the specified channel is completed, the result is sequentially transferred to FIFO and can be accessed only from the A/D data register 0.
3. When more than 4 samples in FIFO, the ADF bit in ADSR is set to 1. If the ADIE bit is set to 1 at this time, an ADC interrupt is requested after finishing the A/D conversion.
4. Steps 2 to 3 are repeated as long as the ADST bit remains set to 1. When the ADST bit is cleared to 0, ADC controller will finish current conversion and enter the idle state (M05xxBN only). But, ADC cannot finish the current conversion and A/D converter enters idle state directly (M05xxDN/DE only).

Note 1: If software enables more than one channel in Burst mode, only the channel with the smallest number is converted and other enabled channels will be ignored.

Note 2: In Burst mode, ADC does not support 2's complement output format, the DMOF bit must be cleared to 0 (M05xxBN only).

By Nuvoton ADC Driver, user can call the flow as shown below to operate Burst mode.

```
/* Set the ADC operation mode as Burst, input mode as single-end and enable the ADC converter */
ADC->ADCR = (ADC_ADCR_ADMD_BURST
                | ADC_ADCR_DIFFEN_SINGLE_END
                | ADC_ADCR_ADEN_CONVERTER_ENABLE);
/* Enable analog input channel 2 */
```

```

_ADC_SET_CHANNEL(1<<2);

/* Clear the A/D interrupt flag for safe */
ADC->ADSR = ADC_ADSR_ADF_Msk;

/* Enable the ADC interrupt */
_ADC_ENABLE_ADC_INT();
NVIC_EnableIRQ(ADC IRQn);

/* start A/D conversion */
_ADC_START_CONVERT();

```

6.14.5.4 Single-Cycle Scan Mode

In Single-cycle Scan mode, A/D converter samples and converts all of the specified channels once in the sequence from the smallest number enabled channel to the largest number enabled channel. Operations are as follows:

1. When the ADST bit in ADCR is set to 1 by software or external trigger input, A/D conversion is started on the channel with the smallest number.
2. When A/D conversion for each enabled channel is completed, the result is sequentially transferred to the A/D data register corresponding to each channel.
3. When the conversions of all the enabled channels are completed, the ADF bit in ADSR is set to 1. If the ADC interrupt function is enabled, the ADC interrupt occurs.
4. After ADC finishes one cycle conversion, the ADST bit is automatically cleared to 0 and the A/D converter enters idle state. If ADST is cleared to 0 before all enabled ADC channels conversion done, ADC controller will finish current conversion and the result of the smallest enabled ADC channel will become unpredictable (M05xxBN only). But, ADC cannot finish the current conversion and A/D converter enters idle state directly (M05xxDN/DE only). Note that after the hardware clears the ADST bit to 0, the ADST bit must be kept at 0 at least one ADC peripheral clock period before setting it to 1 again, otherwise the A/D converter may not work (M05xxBN only).

Through the ADC Driver, user can call the flow as shown below to operate Single-cycle Scan mode.

```

/* Set the ADC operation mode as Single-cycle, input mode as single-end and enable the ADC converter */
ADC->ADCR = (ADC_ADCR_ADMD_SINGLE_CYCLE
              | ADC_ADCR_DIFFEN_SINGLE_END
              | ADC_ADCR_ADEN_CONVERTER_ENABLE);
/* Enable analog input channel 0, 1, 2 and 3 */
_ADC_SET_CHANNEL(0xF);

/* clear the A/D interrupt flag for safe */
ADC->ADSR = ADC_ADSR_ADF_Msk;

/* start A/D conversion */

```

```
_ADC_START_CONVERT();

/* Wait conversion done */

_ADC_WAIT_CONVERSION_DONE();
```

An example timing diagram for Single-cycle Scan mode on enabled channels (0, 2, 3 and 7) is shown below.

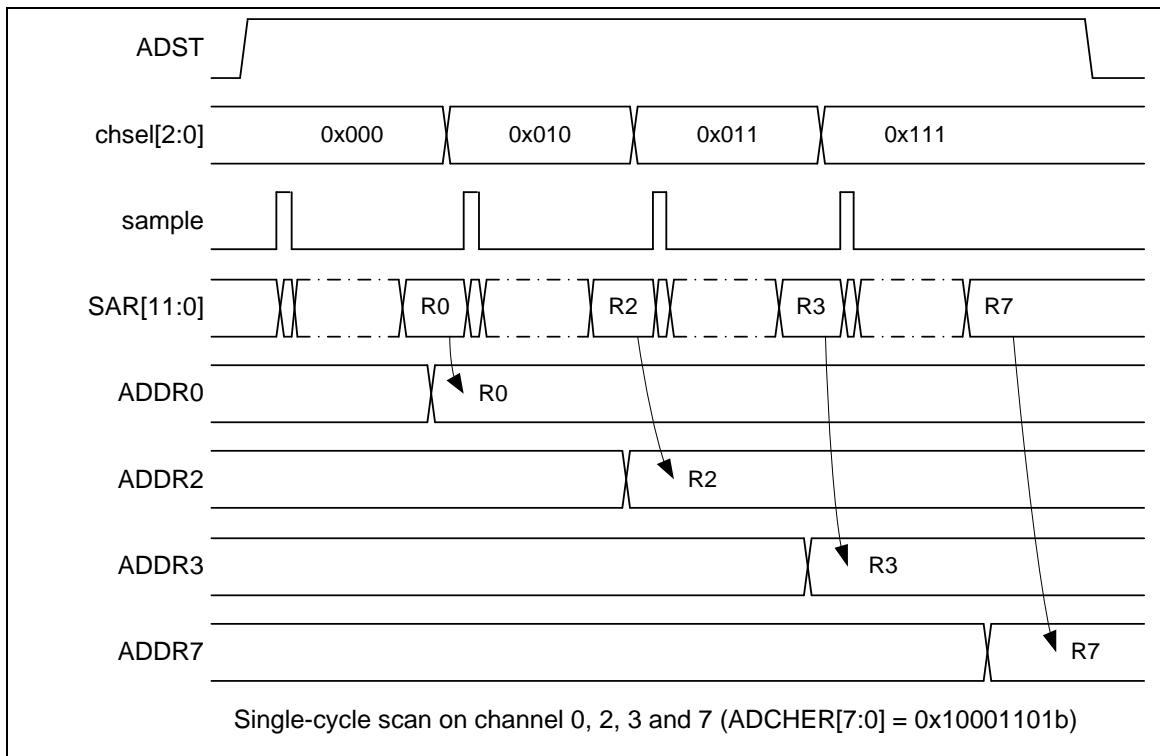

Figure 6-103 Single-Cycle Scan Mode on Enabled Channels Timing Diagram

6.14.5.5 Continuous Scan Mode

In Continuous Scan mode, A/D conversion is performed sequentially on the specified channels that enabled by CHEN bits in ADCHER register (maximum 8 channels for ADC). The operations are as follows:

1. When the ADST bit in ADCR is set to 1 by software or external trigger input, A/D conversion is started on the channel with the smallest number.
2. When A/D conversion for each enabled channel is completed, the result of each enabled channel is stored in the A/D data register corresponding to each enabled channel.
3. When A/D converter completes the conversions of all enabled channels sequentially, the ADF bit (ADSR[0]) will be set to 1. If the ADC interrupt function is enabled, the ADC interrupt occurs. The conversion of the enabled channel with the smallest number will start again if software does not clear the ADST bit.
4. As long as the ADST bit remains at 1, the step 2 ~ 3 will be repeated. When ADST is cleared

to 0, ADC controller will finish the current conversion and the result of the smallest enabled ADC channel will become unpredictable (M05xxBN only). But, ADC cannot finish the current conversion and A/D converter enters idle state directly (M05xxDN/DE only).

Through the ADC Driver, user can call the flow as shown below to operate Continuous Scan mode.

```
/* Set the ADC operation mode as Continuous Scan, input mode as single-end and enable the ADC converter */
ADC->ADCR = (ADC_ADCR_ADMODE_CONTINUOUS
               | ADC_ADCR_DIFFEN_SINGLE_END
               | ADC_ADCR_ADEN_CONVERTER_ENABLE);

/* Enable analog input channel 0, 1, 2 and 3 */
_ADC_SET_CHANNEL(0xF);

/* Clear the A/D interrupt flag for safe */
ADC->ADSR = ADC_ADSR_ADF_Msk;

/* Start A/D conversion */
_ADC_START_CONVERT();

/* Wait conversion done */
_ADC_WAIT_CONVERSION_DONE();

/* Stop A/D conversion */
_ADC_STOP_CONVERT();
```

An example timing diagram for Continuous Scan mode on enabled channels (0, 2, 3 and 7) is shown below.

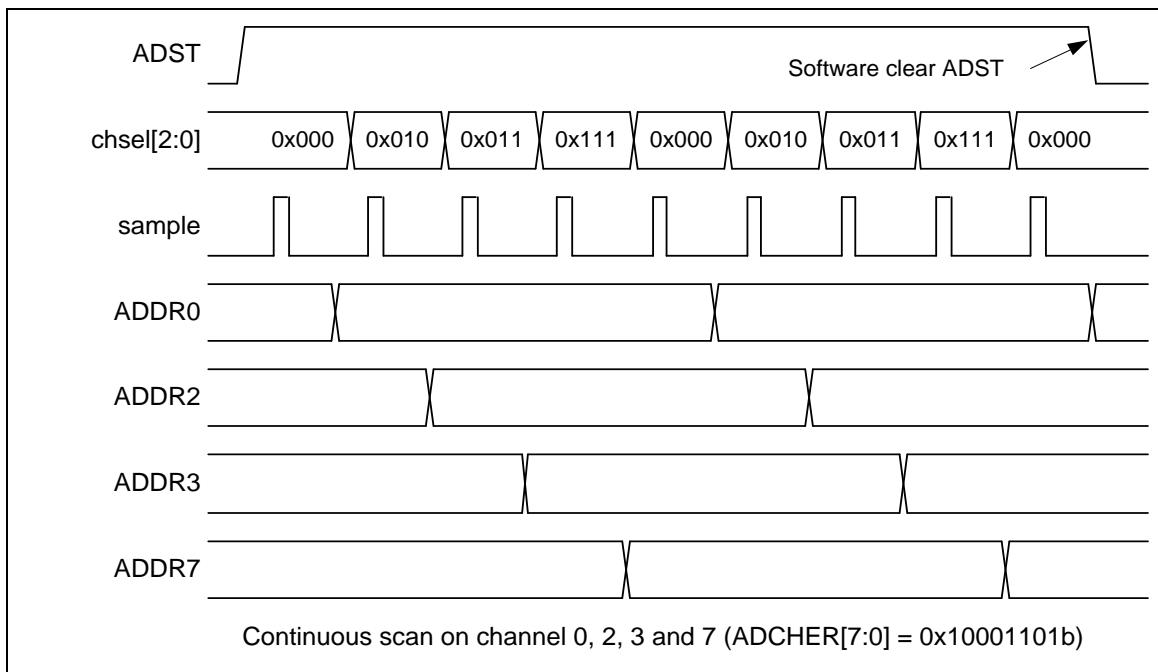

Figure 6-104 Continuous Scan Mode on Enabled Channels Timing Diagram

6.14.5.6 External Trigger Input Sampling and A/D Conversion Time

In Single-cycle Scan mode, A/D conversion can be triggered by external pin request. When the TRGEN bit of ADCR register is set to 1 to enable ADC external trigger function, setting the TRGS[1:0] bits to 00b is to select external trigger input from the STADC pin. Software can set TRGCOND[1:0] to select trigger condition is falling/rising edge or low/high level. If level trigger condition is selected, the STADC pin must be kept at specified state at least 8 PCLKs. The ADST bit will be set to 1 at the 9th PCLK and start to convert. Conversion will keep going if external trigger input is kept at active state in level trigger mode. It is stopped only when external condition trigger condition disappears. If edge trigger condition is selected, the high and low state must be kept at least 4 PLCKs. Pulse that is shorter than this specification will be ignored.

Note: User must enable the external trigger function or enable ADC at least 4 PCLKs after enabling ADC peripheral clock.

6.14.5.7 Internal Reference Voltage

The band-gap voltage reference (V_{BG}) is an internal fixed reference voltage regardless of power supply variations. The V_{BG} output is internally connected to ADC channel 7 source multiplexer and Analog Comparators's (ACMP) negative input side.

For battery power detection application, user can use the V_{BG} as ADC input channel such that user can convert the A/D conversion result to calculate AV_{DD} with following formula.

$$AV_{DD} = ((2^N) / R) * V_{BG}$$

N: ADC resolution

R: A/D conversion result

V_{BG} : Band-gap voltage

The block diagram is shown as Figure 6-105.

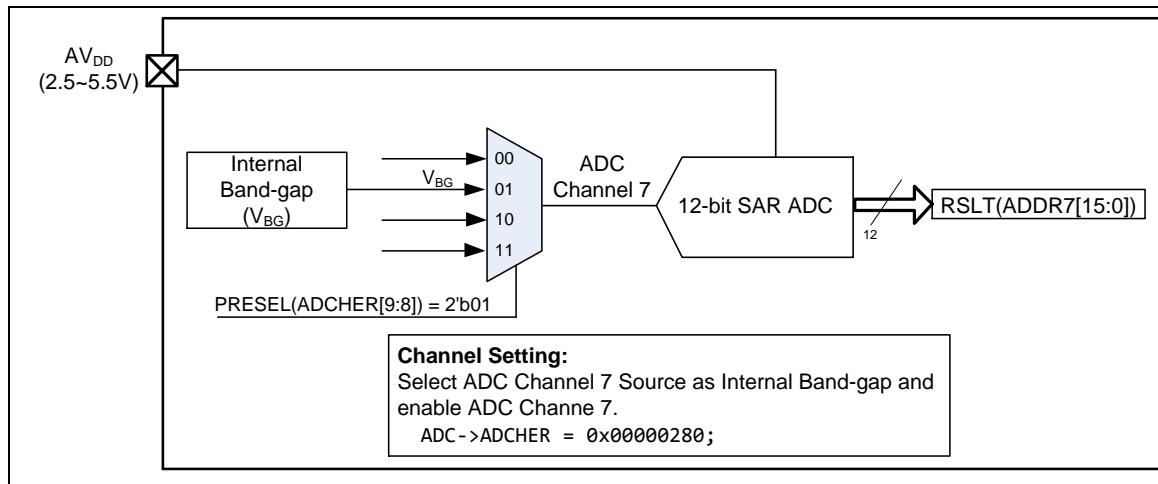

Figure 6-105 V_{BG} for Measuring AV_{DD} Application Block Diagram

For example, the V_{BG} typical value is 1.25 V, the ADC is 12-bit resolution, select V_{BG} as ADC channel 7 input source, and enable ADC channel 7. Then trigger ADC to converse.

If the A/D conversion result is 1707:

$$N = 12$$

$$R = 1707$$

$$V_{BG} = 1.25 \text{ V}$$

$$AV_{DD} = ((2^N) / R) * V_{BG} = (4096 / 1707) * 1.25 = 3 \text{ V}$$

If the A/D conversion result is 2048:

$$AV_{DD} = ((2^N) / R) * V_{BG} = (4096 / 2048) * 1.25 = 2.5 \text{ V}$$

6.14.5.8 PWM trigger

In Single-cycle Scan mode, A/D conversion can be triggered by PWM request (M05xxDN/DE only). When the TRGEN is set to high to enable ADC external hardware trigger function, setting the TRGS[1:0] bits to 11b is to select external hardware trigger input source from PWM trigger. When PWM trigger is enabled, setting PTDT[7:0] bits can insert a delay time between PWM trigger condition and ADC start conversion.

6.14.5.9 Conversion Result Monitor by Compare Mode Function

The NuMicro® M05xxBN/DN/DE series ADC controller provides two compare registers, ADCMPR0 and ADCMPR1, to monitor maximum two specified channels. Software can select which channel to be monitored by setting CMPCH (ADCMRPx[5:0]). CMPCOND bit is used to determine the compare condition. If CMPCOND bit is cleared to 0, the internal match counter will increase one when the conversion result is less than the value specified in CMPD[11:0]; if CMPCOND bit is set to 1, the internal match counter will increase one when the conversion result is greater than or equal to the value specified in CMPD[11:0]. When the conversion of the channel specified by CMPCH is completed, the comparing action will be triggered one time automatically. When the compare result meets the setting, compare match counter will increase 1, otherwise, the compare match counter will be clear to 0. When the match counter reaches the setting of (CMPMATCNT+1) then CMPF bit will be set to 1, if CMPIE bit is set then an ADC_INT interrupt request is generated. Software can use it to monitor the external analog input pin voltage transition in scan mode without imposing a load on software. The detailed logic diagram is shown below.

Note: If user enables differential input mode, the conversion result can be expressed with binary straight format (unsigned format) or 2's complement format (signed format). Software can set DMOF[31] bit of ADSR register to select output format. When differential input mode is enabled, the digital compare function does not support 2's complement output format, the DMOF bit must be cleared to 0 (M05xxBN only).

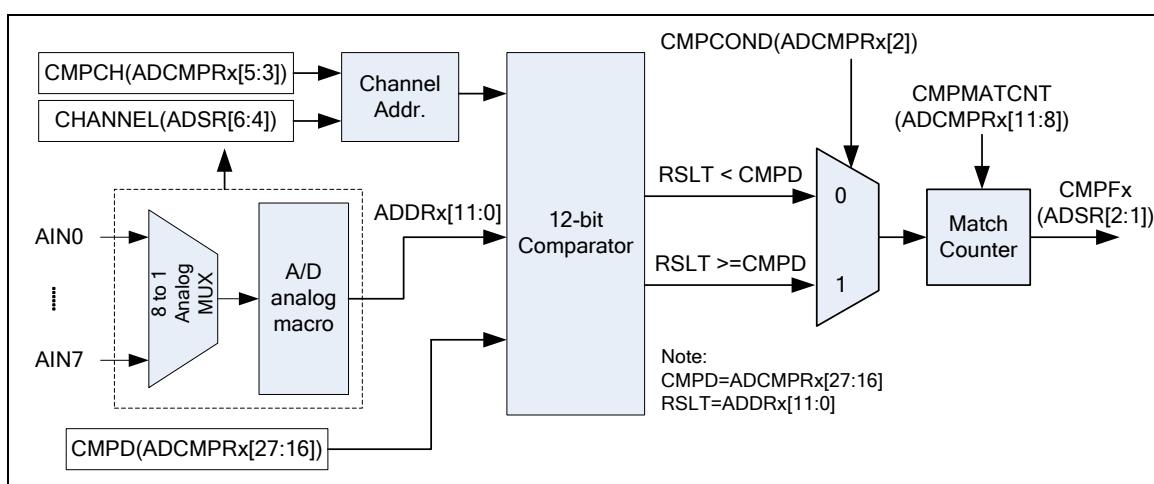

Figure 6-106 A/D Conversion Result Monitor Logic Diagram

6.14.5.10 Interrupt Sources

There are three interrupt sources of ADC interrupt. When an ADC operation mode finishes its conversion, the A/D conversion end flag, ADF, will be set to 1. The CMPF0 and CMPF1 are the compare flags of compare function. When the conversion result meets the settings of ADCMPR0/1, the corresponding flag will be set to 1. When one of the flags, ADF, CMPF0 and CMPF1, is set to 1 and the corresponding interrupt enable bit, ADIE of ADCR and CMPIE of ADCMPR0/1, is set to 1, the ADC interrupt will be asserted. Software can clear these flags to revoke the interrupt request.

RSLT							

Bits	Description	
[31:18]	Reserved	Reserved.
[17]	VALID	Valid Flag 0 = Data in RSLT bits is not valid. 1 = Data in RSLT bits is valid. This bit will be set to 1 when the conversion of the corresponding channel is completed. This bit will be cleared to 0 by hardware after ADDR register is read. This is a read only bit. Note: When ADC is converting, if user wants to monitor the VALID flag of a specified channel, user should poll the VALID bit of ADSR register instead of polling this bit (M05xxBN only).
[16]	OVERRUN	Overrun Flag (Read Only) 0 = Data in RSLT is not overwrote. 1 = Data in RSLT is overwrote. If converted data in RSLT has not been read before new conversion result is loaded to this register, OVERRUN is set to 1. It is cleared by hardware after ADDR register is read.

[15:0]	RSLT	A/D Conversion Result This field contains conversion result of ADC.

6.15 Analog Comparator (ACMP)

6.15.1 Overview

The M05xxBN/DN/DE contains up to four comparators which can be used in a number of different configurations. The comparator output is logic 1 when positive input greater than negative input, otherwise the output is 0. Each comparator can be configured to generate interrupt request when the comparator output value changes.

6.15.2 Features

- Analog input voltage range: $0 \sim AV_{DD}$.
- Supports Hysteresis function
- Optional internal reference voltage source for each comparator negative input
- Two interrupt vectors for the four analog comparators

	M05xxBN	M05xxDN	M05xxDE

6.15.3 Block Diagram

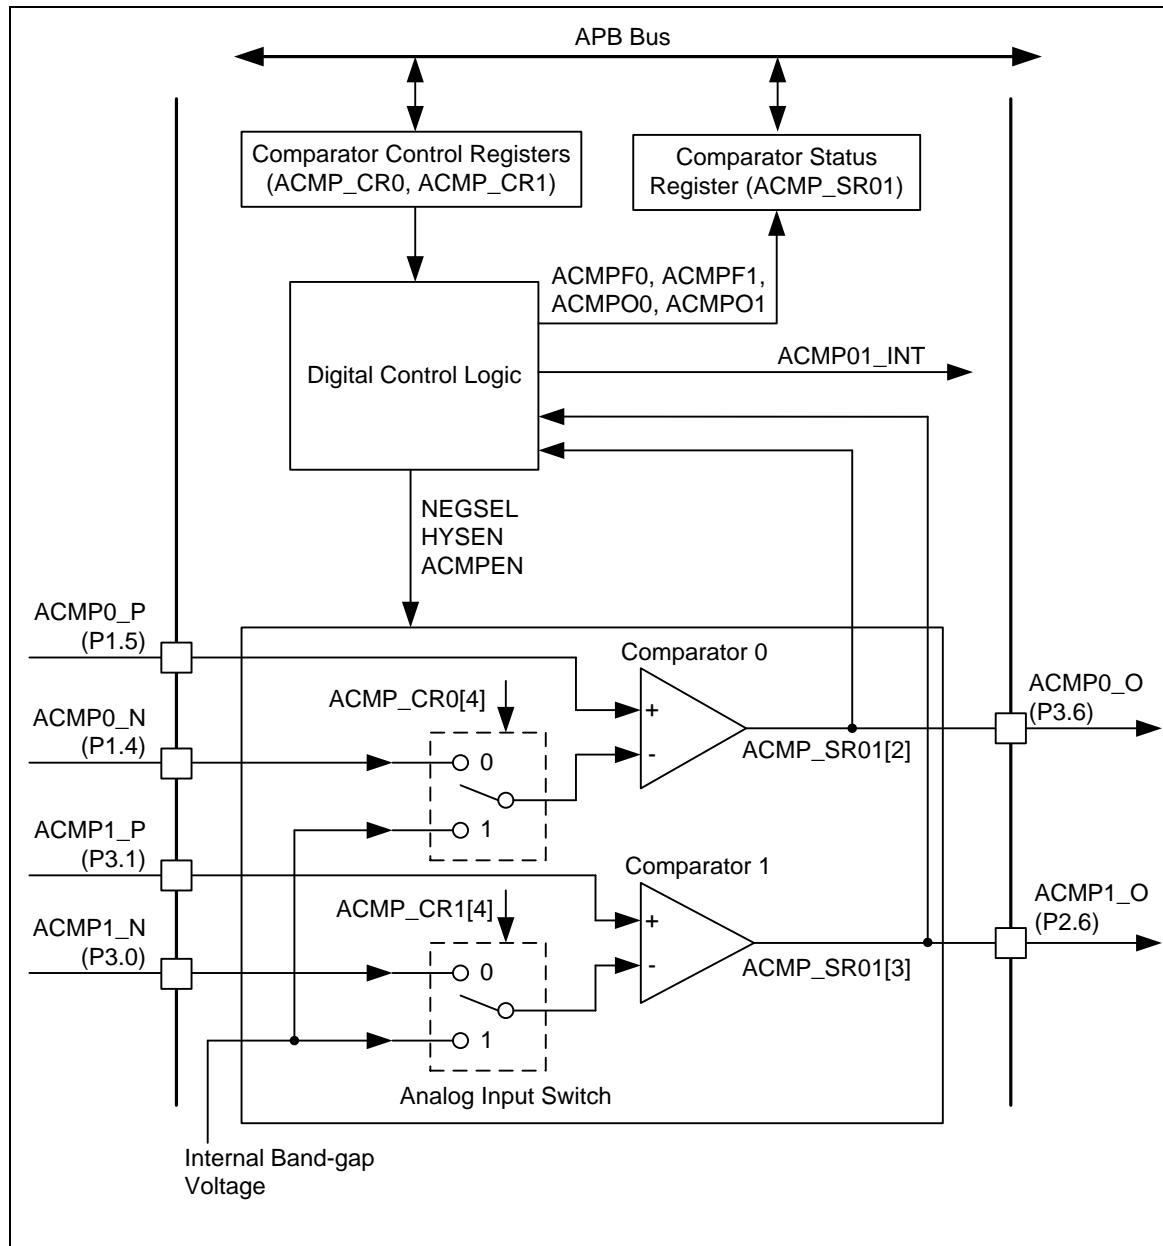

Figure 6-110 Analog Comparator 0/1 Block Diagram

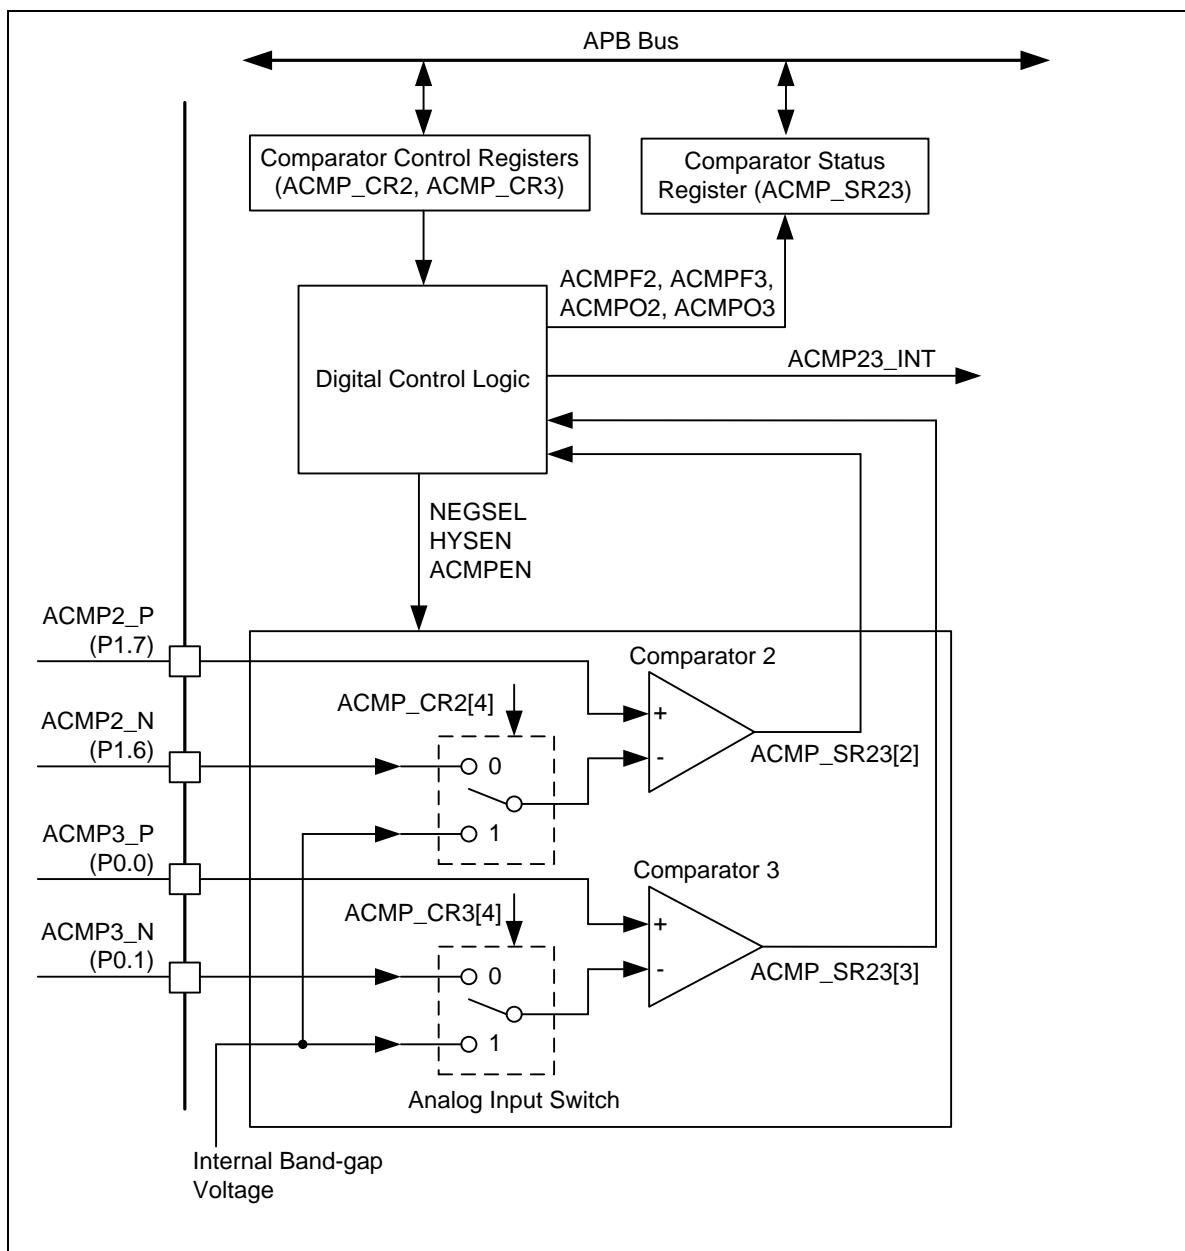

Figure 6-111 Analog Comparator 2/3 Block Diagram (M05xxDN/DE Only)

6.15.4 Basic Configuration

The ACMP pin functions are configured in P0_MFP, P1_MFP, P2_MFP and P3_MFP registers. It is recommended to disable the digital input path of the analog input pins to avoid the leakage current. The digital input path can be disabled by configuring P0_OFFD, P1_OFFD and P3_OFFD registers. If a GPIO pin is configured as an ACMP input pin, this pin should not be set as Push-pull Output mode in the Px_PMD register. Input mode is the safest configuration. If Open-drain Output mode or Quasi-bidirectional mode is selected, do not output 0 on this GPIO pin. The default GPIO output value is 1. The default Px_PMD setting after chip reset is Quasi-bidirectional mode on M05xxBN. The default Px_PMD setting is determined by user configuration on M05xxDN/DE. It could be configured as Input mode or Quasi-bidirectional mode in M05xxDN/DE user configuration.

The ACMP01 and ACMP23 peripheral clocks can be enabled in APBCLK[30] and APBCLK[31].

6.15.5 Functional Description

6.15.5.1 Interrupt Sources

The output of comparators are sampled by PCLK and reflected at ACMPOx of ACMP_SR01/23 register. If ACMPIE of ACMP_CRx register is set to 1, the comparator interrupt will be enabled. As the output state of comparator is changed, the comparator interrupt will be asserted and the corresponding flag, ACMPFx, will be set. Software can clear the flag to 0 by writing 1 to it.

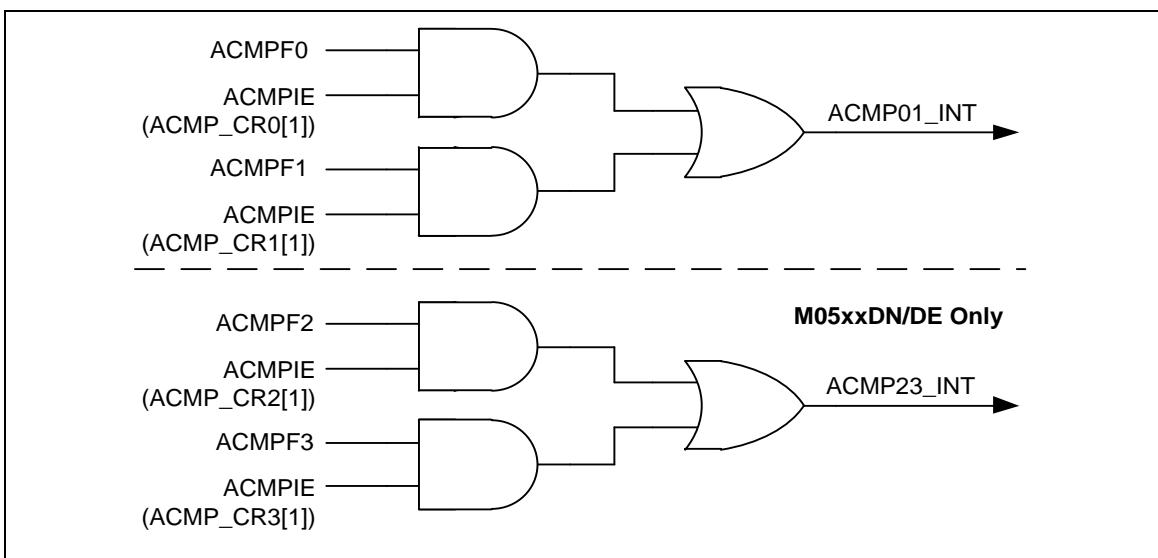

Figure 6-112 Analog Comparator Controller Interrupt Sources

6.15.5.2 Hysteresis Function

The analog comparator provides hysteresis function to make the comparator output transition more stable. If comparator output is 0, it will not change to 1 until the positive input voltage exceeds the negative input voltage by a positive hysteresis voltage. Similarly, if comparator output is 1, it will not change to 0 until the positive input voltage drops below the negative input voltage by a negative hysteresis voltage.

6.16 Hardware Divider (HDIV) (M05xxDN/DE Only)

6.16.1 Overview

The hardware divider (HDIV) is useful to the high performance application. The hardware divider is a signed, integer divider with both quotient and remainder outputs. The hardware divider function is only available on M05xxDN/DE.

6.16.2 Features

- Signed (two's complement) integer calculation
- 32-bit dividend with 16-bit divisor calculation capacity
- 32-bit quotient and 32-bit remainder outputs (16-bit remainder with sign extends to 32-bit)
- Divided by zero warning flag
- 6 HCLK clocks taken for one cycle calculation
- Write divisor to trigger calculation
- Waiting for calculation ready automatically when reading quotient and remainder

6.16.3 Basic Configuration

Before using the hardware divider, the clock of hardware divider must be enabled. To enable hardware divider, it needs to set HDIV_EN on AHBCLK[4] to 1.

6.16.4 Functional Description

To use hardware divider, it needs to set dividend first. Then set divisor and the hardware divider will trigger calculation automatically after divisor written. The calculation results including the quotient and remainder could be got by reading DIVQUO and DIVREM register. If CPU reads DIVQUO or DIVREM before hardware divider calculation finishing, CPU will be held until hardware divider finishing the calculation. Therefore, CPU can always get valid results after trigger one hardware divider calculation without software delay.

DIV0 flag of DIVSTS will be set if divisor is 0.

The dividend is 32-bit signed integer and divisor is 16-bit signed integer. The quotient is 32-bit signed integer and the remainder is 16-bit signed integer.

The following figure shows the operation flow of hardware divider. To calculate X / Y , CPU needs to write X to DIVIDEND register, and then write Y to DIVISOR. CPU can read DIVQUO and DIVREM registers to get calculation results after DIVISOR been written.

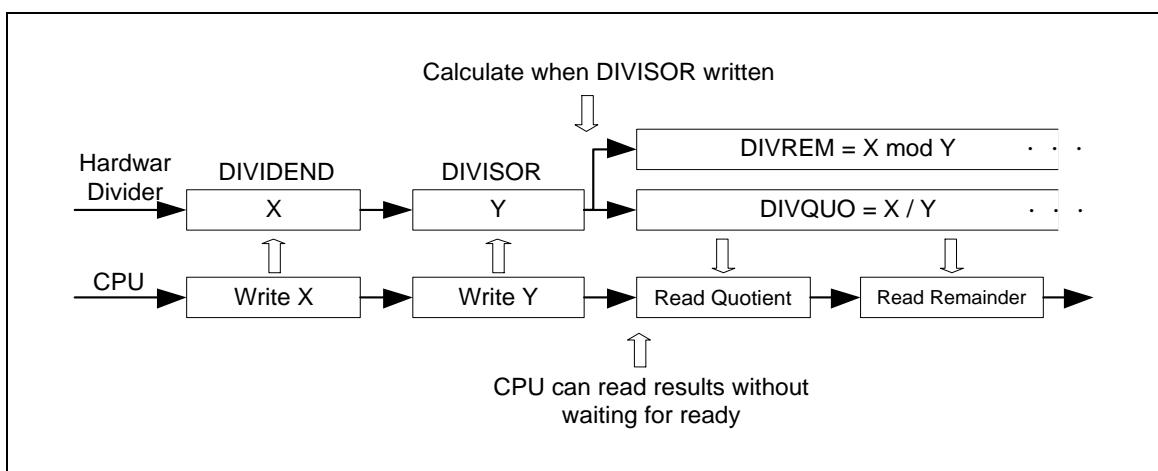

Figure 6-114 Hardware Divider Operation Flow

Bits	Description	
[31:16]	Reserved	Reserved.
[15:0]	DIVISOR	Divisor Source This register is given the divisor of divider before calculation starts. Note: When this register is written, hardware divider will start calculate.

Quotient Result Register (DIVQUO)

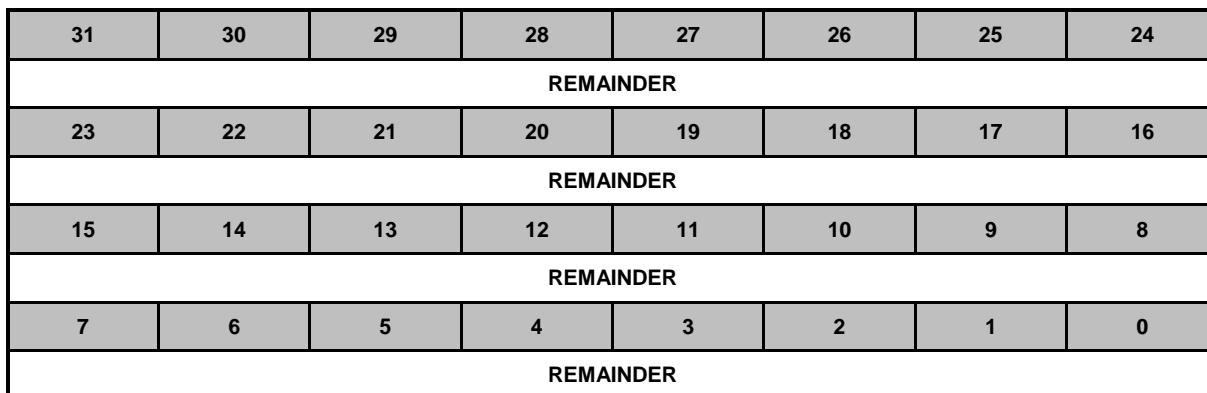

Register	Offset	R/W	Description					Reset Value
DIVQUO	HDIV_BA+0x08	R/W	Quotient Result Register					0x0000_0000

31	30	29	28	27	26	25	24
QUOTIENT							
23	22	21	20	19	18	17	16
QUOTIENT							
15	14	13	12	11	10	9	8
QUOTIENT							
7	6	5	4	3	2	1	0
QUOTIENT							

Bits	Description	
[31:0]	QUOTIENT	Quotient Result This register holds the quotient result of divider after calculation complete.

Remainder Result Register (DIVREM)

Register	Offset	R/W	Description					Reset Value
DIVREM	HDIV_BA+0x0C	R/W	Remainder Result Register					0x0000_0000

Bits	Description	
[31:16]	REMAINDER[31:16]	Sign Extension of REMAINDER[15:0] The remainder of hardware divider is 16-bit sign integer (REMAINDER[15:0]) with sign extension (REMAINDER[31:16]) to 32-bit integer.
[15:0]	REMAINDER[15:0]	Remainder Result This register holds the remainder result of divider after calculation complete.

Divider Status Register (DIVSTS)

Register	Offset	R/W	Description					Reset Value
DIVSTS	HDIV_BA+0x10	R	Divider Status Register					0x0000_0001

31	30	29	28	27	26	25	24	
Reserved								
23	22	21	20	19	18	17	16	
Reserved								
15	14	13	12	11	10	9	8	
Reserved								
7	6	5	4	3	2	1	0	
Reserved							DIV0	Reserved

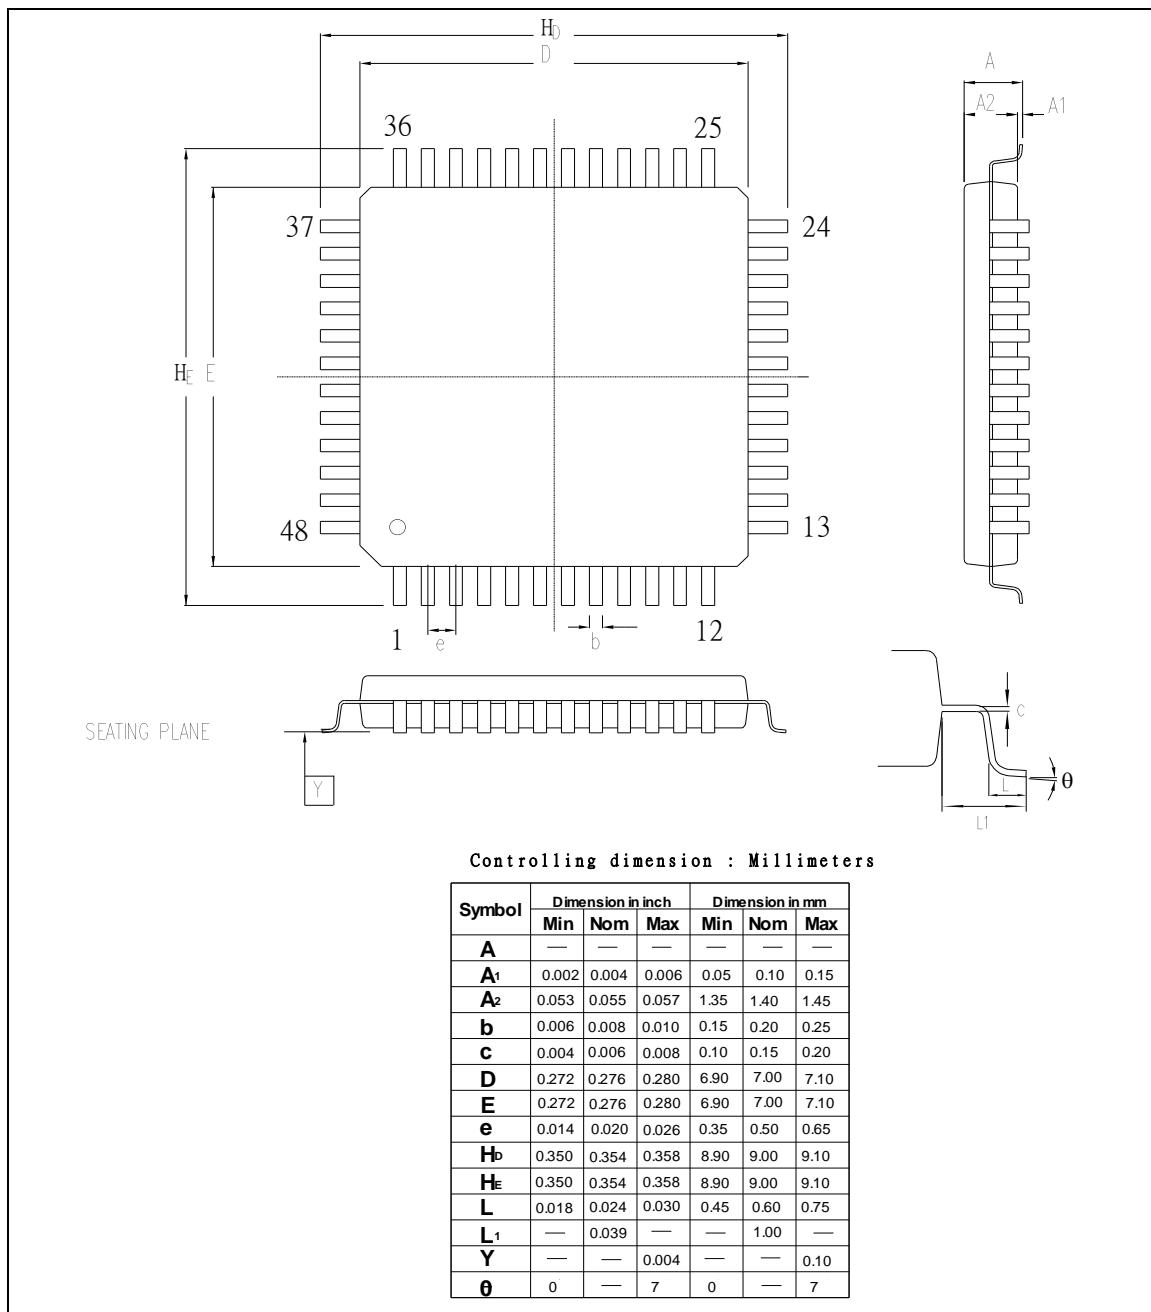

Bits	Description	
[31:2]	Reserved	Reserved.
[1]	DIV0	Divisor Zero Warning 0 = The divisor is not 0. 1 = The divisor is 0. Note: The DIV0 flag is used to indicate divide-by-zero situation and updated whenever DIVISOR is written. This register is read only.
[0]	Reserved	Reserved.

7 ELECTRICAL CHARACTERISTICS

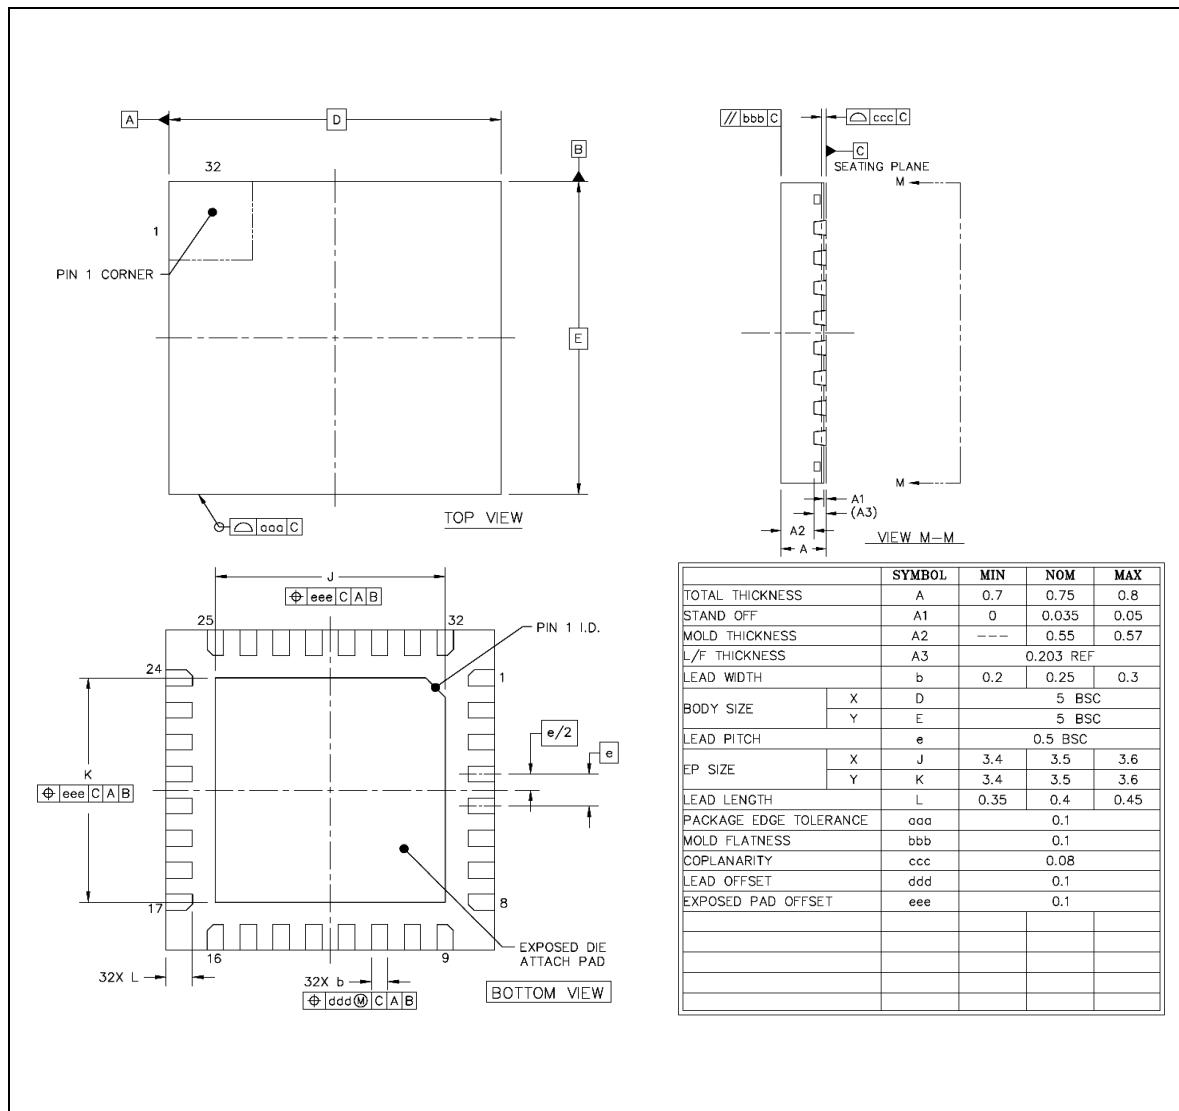

Please refer to the relative Datasheet for detailed information about the M051 Series electrical characteristics.

8 PACKAGE DIMENSIONS

8.1 LQFP-48 (7x7x1.4mm² Footprint 2.0mm)

8.2 QFN-33 (5X5 mm², Thickness 0.8mm, Pitch 0.5 mm)

9 REVISION HISTORY

Date	Revision	Description
2013.09.15	1.00	<ul style="list-style-type: none"> 1. Initially issued.
2015.05.12	1.01	<ul style="list-style-type: none"> 1. Changed the order of Chapter 5 BLOCK DIAGRAM and Chapter 6 FUNCTIONAL DESCRIPTION. 2. Fixed typos and obscure description. 3. Fixed the number of COMP. sets in 4.2 NuMicro® M051 Series M05xxDN Selection Guide and 4.3 NuMicro® M051 Series M05xxDE Selection Guide. 4. Added pin diagram note in Figure 4-2 NuMicro® M051 Series QFN-33 Pin Diagram and Figure 4-3 NuMicro® M051 Series LQFP-48 Pin Diagram. 5. Added clock switching note in Chapter 6.3 Clock Controller. 6. Removed description about ACMP output inverse function available on M05xxDN.
2015.10.05	1.02	<ul style="list-style-type: none"> 1. Changed NuMicro™ to NuMicro®. 2. Added M051xxDN series to supporting list in register description of ACMP23_EN(APBCLK[31]) in 6.3.6 Register Description. 3. Added M051xxDN series to supporting list in register description of I2C1_EN(APBCLK[9]) in 6.3.6 Register Description. 4. Added M051xxDN series to supporting list in Figure 6-112 Analog Comparator Controller Interrupt Sources. 5. Added M051xxDN series to clock source from LIRC supporting list in register description of PWM23_S(CLKSEL1[31:30]), PWM01_S(CLKSEL1[29:28]), PWM67_S(CLKSEL2[7:6]) and PWM45_S(CLKSEL2[5:4]) in 6.3.6 Register Description. 6. Changed the register description of P4_ALT(P4_MFP[3]) in 6.2.6 System Manager Controller Register Map.
2016.04.13	1.03	<ul style="list-style-type: none"> 1. Added Section 6.2.11 Register Protection. 2. Fixed the error about AV_{DD} and V_{REF} mark in Figure 6-100 AD Controller Block Diagram. 3. Added Section 6.14.5.7 Internal Reference Voltage.

Important Notice

Nuvoton Products are neither intended nor warranted for usage in systems or equipment, any malfunction or failure of which may cause loss of human life, bodily injury or severe property damage. Such applications are deemed, "Insecure Usage".

Insecure usage includes, but is not limited to: equipment for surgical implementation, atomic energy control instruments, airplane or spaceship instruments, the control or operation of dynamic, brake or safety systems designed for vehicular use, traffic signal instruments, all types of safety devices, and other applications intended to support or sustain life.

All Insecure Usage shall be made at customer's risk, and in the event that third parties lay claims to Nuvoton as a result of customer's Insecure Usage, customer shall indemnify the damages and liabilities thus incurred by Nuvoton.

Please note that all data and specifications are subject to change without notice.
All the trademarks of products and companies mentioned in this datasheet belong to their respective owners.
